# Subsystems of Second Order Arithmetic

**Second Edition**

Foundations of mathematics is the study of the most basic concepts and logical structure of mathematics, with an eye to the unity of human knowledge. Almost all of the problems studied in this book are motivated by an overriding foundational question: What are the appropriate axioms for mathematics? Through a series of case studies, these axioms are examined to prove particular theorems in core mathematical areas such as algebra, analysis, and topology, focusing on the language of second order arithmetic, the weakest language rich enough to express and develop the bulk of mathematics.

In many cases, if a mathematical theorem is proved from appropriately weak set existence axioms, then the axioms will be logically equivalent to the theorem. Furthermore, only a few specific set existence axioms arise repeatedly in this context, which in turn correspond to classical foundational programs. This is the theme of reverse mathematics, which dominates the first half of the book. The second part focuses on models of these and other subsystems of second order arithmetic. Additional results are presented in an appendix.

Stephen G. Simpson is a mathematician and professor at Pennsylvania State University. The winner of the Grove Award for Interdisciplinary Research Initiation, Simpson specializes in research involving mathematical logic, foundations of mathematics, and combinatorics.

PERSPECTIVES IN LOGIC

The *Perspectives in Logic* series publishes substantial, high-quality books whose central theme lies in any area or aspect of logic. Works that present new material not available in book form are particularly welcome. The series ranges from introductory texts suitable for beginning graduate courses to specialized monographs at the frontiers of research. Each book offers an illuminating perspective for its intended audience.

The series has its origins in the old *Perspectives in Mathematical Logic* series edited by the Ω-Group for "Mathematische Logik" of the Heidelberger Akademie der Wissenchaften, whose beginnings date back to the 1960s. The Association for Symbolic Logic has assumed editorial responsibility for the series and changed its name to reflect its interest in books that span the full range of disciplines in which logic plays an important role.

# PREFACE

Foundations of mathematics is the study of the most basic concepts and logical structure of mathematics, with an eye to the unity of human knowledge. Among the most basic mathematical concepts are: number, shape, set, function, algorithm, mathematical axiom, mathematical definition, and mathematical proof. Typical questions in foundations of mathematics include: What is a number? What is a shape? What is a set? What is a function? What is an algorithm? What is a mathematical axiom? What is a mathematical definition? What is a mathematical proof? What are the most basic concepts of mathematics? What is the logical structure of mathematics? What are the appropriate axioms for numbers? What are the appropriate axioms for shapes? What are the appropriate axioms for sets? What are the appropriate axioms for functions?

Obviously, foundations of mathematics is a subject of the greatest mathematical and philosophical importance. Beyond this, foundations of mathematics is a rich subject with a long history, going back to Aristotle and Euclid and continuing in the hands of outstanding modern figures such as Descartes, Cauchy, Weierstraß, Dedekind, Peano, Frege, Russell, Cantor, Hilbert, Brouwer, Weyl, von Neumann, Skolem, Tarski, Heyting, and Gödel. An excellent reference for the modern era in foundations of mathematics is van Heijenoort [272].

In the late 19th and early 20th centuries, virtually all leading mathematicians were intensely interested in foundations of mathematics and spoke and wrote extensively on this subject. Today that is no longer the case. Regrettably, foundations of mathematics is now out of fashion. Today, most of the leading mathematicians are ignorant of foundations and focus mostly on structural questions. Today, foundations of mathematics is out of favor even among mathematical logicians, the majority of whom prefer to concentrate on methodological or other non-foundational issues.

This book is a contribution to foundations of mathematics. Almost all of the problems studied in this book are motivated by an overriding foundational question: *What are the appropriate axioms for mathematics*? We undertake a series of case studies to discover which are the appropriate axioms for proving particular theorems in core mathematical areas such

as algebra, analysis, and topology. We focus on the language of second order arithmetic, because that language is the weakest one that is rich enough to express and develop the bulk of core mathematics. It turns out that, in many particular cases, if a mathematical theorem is proved from appropriately weak set existence axioms, then the axioms will be logically equivalent to the theorem. Furthermore, only a few specific set existence axioms arise repeatedly in this context: recursive comprehension, weak König's lemma, arithmetical comprehension, arithmetical transfinite recursion, $\Pi^1_1$ comprehension; corresponding to the formal systems $\mathsf{RCA}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$, $\Pi^1_1$-$\mathsf{CA}_0$; which in turn correspond to classical foundational programs: constructivism, finitistic reductionism, predicativism, and predicative reductionism. This is the theme of Reverse Mathematics, which dominates Part A of this book. Part B focuses on models of these and other subsystems of second order arithmetic. Additional results are presented in an appendix.

The formalization of mathematics within second order arithmetic goes back to Dedekind and was developed by Hilbert and Bernays [115, supplement IV]. The present book may be viewed as a continuation of Hilbert/Bernays [115]. I hope that the present book will help to revive the study of foundations of mathematics and thereby earn for itself a permanent place in the history of the subject.

The first edition of this book [249] was published in January 1999. The second edition differs from the first only in that I have corrected some typographical errors and updated some bibliographical entries. Recent advances are in research papers by numerous authors, published in *Reverse Mathematics* 2001 [228] and in scholarly journals. The Web page for this book is `http://www.math.psu.edu/simpson/sosoa/`. I would like to develop this Web page into a forum for research and scholarship, not only in subsystems of second order arithmetic, but in foundations of mathematics generally.

Stephen G. Simpson

# ACKNOWLEDGMENTS

Much of my work on subsystems of second order arithmetic has been carried on in collaboration with my doctoral and postdoctoral advisees at Berkeley and Penn State, including: Stephen Binns, Stephen Brackin, Douglas Brown, Natasha Dobrinen, Qi Feng, Fernando Ferreira, Mariagnese Giusto, Kostas Hatzikiriakou, Jeffry Hirst, James Humphreys, Michael Jamieson, Alberto Marcone, Carl Mummert, Ju Rao, Rick Smith, John Steel, Kazuyuki Tanaka, Robert Van Wesep, Galen Weitkamp, Takeshi Yamazaki, and Xiaokang Yu. I also acknowledge the collaboration and encouragement of numerous colleagues including: Peter Aczel, Jeremy Avigad, Jon Barwise, Michael Beeson, Errett Bishop, Andreas Blass, Lenore Blum, Douglas Bridges, Wilfried Buchholz, John Burgess, Samuel Buss, Douglas Cenzer, Peter Cholak, Chi-Tat Chong, Rolando Chuaqui, John Clemens, Peter Clote, Carlos Di Prisco, Rod Downey, Ali Enayat, Herbert Enderton, Harvey Friedman, Robin Gandy, William Gasarch, Noam Greenberg, Petr Hájek, Valentina Harizanov, Victor Harnik, Leo Harrington, Christoph Heinatsch, Ward Henson, Peter Hinman, Denis Hirschfeldt, William Howard, Martin Hyland, Gerhard Jäger, Haim Judah, Irving Kaplansky, Alexander Kechris, Jerome Keisler, Jeffrey Ketland, Bjørn Kjos-Hanssen, Stephen Kleene, Julia Knight, Ulrich Kohlenbach, Roman Kossak, Georg Kreisel, Antonín Kučera, Masahiro Kumabe, Richard Laver, Steffen Lempp, Manuel Lerman, Azriel Lévy, Alain Louveau, Angus Macintyre, Michael Makkai, Richard Mansfield, David Marker, Donald Martin, Adrian Mathias, Alex McAllister, Kenneth McAloon, Timothy McNicholl, George Metakides, Joseph Mileti, Joseph Miller, Grigori Mints, Michael Möllerfeld, Antonio Montalban, Yiannis Moschovakis, Gert Müller, Roman Murawski, Jan Mycielski, Michael Mytilinaios, Anil Nerode, Andre Nies, Charles Parsons, Marian Pour-El, Michael Rathjen, Jeffrey Remmel, Jean-Pierre Ressayre, Ian Richards, Hartley Rogers, Gerald Sacks, Ramez Sami, Andre Scedrov, James Schmerl, Kurt Schütte, Helmut Schwichtenberg, Dana Scott, Saharon Shelah, John Shepherdson, Naoki Shioji, Joseph Shoenfield, Richard Shore, Wilfried Sieg, Jack Silver, Ksenija Simic, Theodore Slaman, Craig Smoryński, Robert Soare, Reed Solomon, Robert Solovay,

Rick Sommer, Andrea Sorbi, Gaisi Takeuti, Dirk van Dalen, Lou van den Dries, Daniel Velleman, Stanley Wainer, Dongping Yang, Yue Yang, and especially Solomon Feferman, Carl Jockusch, and Wolfram Pohlers.

I acknowledge the help of various institutions including: the Alfred P. Sloan Foundation, the American Mathematical Society, the Association for Symbolic Logic, the Centre National de Recherche Scientifique, the Deutsche Forschungsgemeinschaft, the National Science Foundation, the Omega Group, Oxford University, the Pennsylvania State University, the Raymond N. Shibley Foundation, the Science Research Council, Springer-Verlag, Stanford University, the University of California at Berkeley, the University of Illinois at Urbana–Champaign, the University of Munich, the University of Paris, the University of Tennessee, and the Volkswagen Foundation.

A preliminary version of this book was written with a software package called MathText. I acknowledge important help from Robert Huff, the author of MathText, and Janet Huff. Padma Raghavan wrote additional software to help me convert the manuscript from MathText to LaTeX. The first edition [249] was published by Springer-Verlag with editorial assistance from the Association for Symbolic Logic. The second edition is being published by the Association for Symbolic Logic and Cambridge University Press. I acknowledge help from Samuel Buss, Ward Henson, Reinhard Kahle, Steffen Lempp, Manuel Lerman, and Thanh-Ha LeThi.

I thank my darling wife, Padma Raghavan, for her encouragement and emotional support while I was bringing this project to a conclusion, both in 1997–1998 and again in 2008.

Chapter I

# INTRODUCTION

## I.1. The Main Question

The purpose of this book is to use the tools of mathematical logic to study certain problems in foundations of mathematics. We are especially interested in the question of which set existence axioms are needed to prove the known theorems of mathematics.

The scope of this initial question is very broad, but we can narrow it down somewhat by dividing mathematics into two parts. On the one hand there is set-theoretic mathematics, and on the other hand there is what we call "non-set-theoretic" or "ordinary" mathematics. By *set-theoretic mathematics* we mean those branches of mathematics that were created by the set-theoretic revolution which took place approximately a century ago. We have in mind such branches as general topology, abstract functional analysis, the study of uncountable discrete algebraic structures, and of course abstract set theory itself.

We identify as *ordinary* or *non-set-theoretic* that body of mathematics which is prior to or independent of the introduction of abstract set-theoretic concepts. We have in mind such branches as geometry, number theory, calculus, differential equations, real and complex analysis, countable algebra, the topology of complete separable metric spaces, mathematical logic, and computability theory.

The distinction between set-theoretic and ordinary mathematics corresponds roughly to the distinction between "uncountable mathematics" and "countable mathematics". This formulation is valid if we stipulate that "countable mathematics" includes the study of possibly uncountable complete separable metric spaces. (A metric space is said to be separable if it has a countable dense subset.) Thus for instance the study of continuous functions of a real variable is certainly part of ordinary mathematics, even though it involves an uncountable algebraic structure, namely the real number system. The point is that in ordinary mathematics, the real line partakes of countability since it is always viewed as a separable metric space, never as being endowed with the discrete topology.

In this book we want to restrict our attention to ordinary, non-set-theoretic mathematics. The reason for this restriction is that the set existence axioms which are needed for set-theoretic mathematics are likely to be much stronger than those which are needed for ordinary mathematics. Thus our broad set existence question really consists of two subquestions which have little to do with each other. Furthermore, while nobody doubts the importance of strong set existence axioms in set theory itself and in set-theoretic mathematics generally, the role of set existence axioms in ordinary mathematics is much more problematical and interesting.

We therefore formulate our *Main Question* as follows: *Which set existence axioms are needed to prove the theorems of ordinary, non-set-theoretic mathematics*?

In any investigation of the Main Question, there arises the problem of choosing an appropriate language and appropriate set existence axioms. Since in ordinary mathematics the objects studied are almost always countable or separable, it would seem appropriate to consider a language in which countable objects occupy center stage. For this reason, we study the Main Question in the context of the language of second order arithmetic. This language is denoted $L_2$ and will be described in the next section. All of the set existence axioms which we consider in this book will be expressed as formulas of the language $L_2$.

## I.2. Subsystems of $Z_2$

In this section we define $Z_2$, the formal system of second order arithmetic. We also introduce the concept of a subsystem of $Z_2$.

The *language of second order arithmetic* is a two-sorted language. This means that there are two distinct sorts of variables which are intended to range over two different kinds of object. Variables of the first sort are known as *number variables*, are denoted by $i, j, k, m, n, \ldots$, and are intended to range over the set $\omega = \{0, 1, 2, \ldots\}$ of all natural numbers. Variables of the second sort are known as *set variables*, are denoted by $X, Y, Z, \ldots$, and are intended to range over all subsets of $\omega$.

The terms and formulas of the language of second order arithmetic are as follows. *Numerical terms* are number variables, the constant symbols 0 and 1, and $t_1 + t_2$ and $t_1 \cdot t_2$ whenever $t_1$ and $t_2$ are numerical terms. Here $+$ and $\cdot$ are binary operation symbols intended to denote addition and multiplication of natural numbers. (Numerical terms are intended to denote natural numbers.) *Atomic formulas* are $t_1 = t_2$, $t_1 < t_2$, and $t_1 \in X$ where $t_1$ and $t_2$ are numerical terms and $X$ is any set variable. (The intended meanings of these respective atomic formulas are that $t_1$ equals $t_2$, $t_1$ is less than $t_2$, and $t_1$ is an element of $X$.) *Formulas* are built up from atomic formulas by means of propositional connectives $\wedge$, $\vee$, $\neg$, $\rightarrow$,

$\leftrightarrow$ (and, or, not, implies, if and only if), *number quantifiers* $\forall n$, $\exists n$ (for all $n$, there exists $n$), and *set quantifiers* $\forall X$, $\exists X$ (for all $X$, there exists $X$). A *sentence* is a formula with no free variables.

DEFINITION I.2.1 (language of second order arithmetic). $L_2$ is defined to be the language of second order arithmetic as described above.

In writing terms and formulas of $L_2$, we shall use parentheses and brackets to indicate grouping, as is customary in mathematical logic textbooks. We shall also use some obvious abbreviations. For instance, $2 + 2 = 4$ stands for $(1 + 1) + (1 + 1) = ((1 + 1) + 1) + 1$, $(m + n)^2 \notin X$ stands for $\neg((m + n) \cdot (m + n) \in X)$, $s \leq t$ stands for $s < t \vee s = t$, and $\varphi \wedge \psi \wedge \theta$ stands for $(\varphi \wedge \psi) \wedge \theta$.

The semantics of the language $L_2$ are given by the following definition.

DEFINITION I.2.2 ($L_2$-structures). A *model for* $L_2$, also called a *structure for* $L_2$ or an $L_2$-*structure*, is an ordered 7-tuple

$$M = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M),$$

where $|M|$ is a set which serves as the range of the number variables, $\mathcal{S}_M$ is a set of subsets of $|M|$ serving as the range of the set variables, $+_M$ and $\cdot_M$ are binary operations on $|M|$, $0_M$ and $1_M$ are distinguished elements of $|M|$, and $<_M$ is a binary relation on $|M|$. We always assume that the sets $|M|$ and $\mathcal{S}_M$ are disjoint and nonempty. Formulas of $L_2$ are interpreted in $M$ in the obvious way.

In discussing a particular model $M$ as above, it is useful to consider formulas with parameters from $|M| \cup \mathcal{S}_M$. We make the following slightly more general definition.

DEFINITION I.2.3 (parameters). Let $\mathcal{B}$ be any subset of $|M| \cup \mathcal{S}_M$. By a *formula with parameters from* $\mathcal{B}$ we mean a formula of the extended language $L_2(\mathcal{B})$. Here $L_2(\mathcal{B})$ consists of $L_2$ augmented by new constant symbols corresponding to the elements of $\mathcal{B}$. By a *sentence with parameters from* $\mathcal{B}$ we mean a sentence of $L_2(\mathcal{B})$, i.e., a formula of $L_2(\mathcal{B})$ which has no free variables.

In the language $L_2(|M| \cup \mathcal{S}_M)$, constant symbols corresponding to elements of $\mathcal{S}_M$ (respectively $|M|$) are treated syntactically as unquantified set variables (respectively unquantified number variables). Sentences and formulas with parameters from $|M| \cup \mathcal{S}_M$ are interpreted in $M$ in the obvious way. A set $A \subseteq |M|$ is said to be *definable over* $M$ *allowing parameters from* $\mathcal{B}$ if there exists a formula $\varphi(n)$ with parameters from $\mathcal{B}$ and no free variables other than $n$ such that

$$A = \{a \in |M| : M \models \varphi(a)\}.$$

Here $M \models \varphi(a)$ means that $M$ *satisfies* $\varphi(a)$, i.e., $\varphi(a)$ is true in $M$.

We now discuss some specific $L_2$-structures. The *intended model* for $L_2$ is of course the model

$$(\omega, P(\omega), +, \cdot, 0, 1, <)$$

where $\omega$ is the set of natural numbers, $P(\omega)$ is the set of all subsets of $\omega$, and $+, \cdot, 0, 1, <$ are as usual. By an *$\omega$-model* we mean an $L_2$-structure of the form

$$(\omega, \mathcal{S}, +, \cdot, 0, 1, <)$$

where $\emptyset \neq \mathcal{S} \subseteq P(\omega)$. Thus an $\omega$-model differs from the intended model only by having a possibly smaller collection $\mathcal{S}$ of sets to serve as the range of the set variables. We sometimes speak of the *$\omega$-model $\mathcal{S}$* when we really mean the $\omega$-model $(\omega, \mathcal{S}, +, \cdot, 0, 1, <)$. In some parts of this book we shall be concerned with a special class of $\omega$-models known as $\beta$-models. This class will be defined in §I.5.

We now present the formal system of second order arithmetic.

DEFINITION I.2.4 (second order arithmetic). The *axioms of second order arithmetic* consist of the universal closures of the following $L_2$-formulas:

(i) basic axioms:

$$\begin{aligned}
&n + 1 \neq 0\\
&m + 1 = n + 1 \rightarrow m = n\\
&m + 0 = m\\
&m + (n + 1) = (m + n) + 1\\
&m \cdot 0 = 0\\
&m \cdot (n + 1) = (m \cdot n) + m\\
&\neg m < 0\\
&m < n + 1 \leftrightarrow (m < n \vee m = n)
\end{aligned}$$

(ii) induction axiom:

$$(0 \in X \wedge \forall n\,(n \in X \rightarrow n + 1 \in X)) \rightarrow \forall n\,(n \in X)$$

(iii) comprehension scheme:

$$\exists X\,\forall n\,(n \in X \leftrightarrow \varphi(n))$$

where $\varphi(n)$ is any formula of $L_2$ in which $X$ does not occur freely.

Intuitively, the given instance of the comprehension scheme says that there exists a set $X = \{n\colon \varphi(n)\}$ = the set of all $n$ such that $\varphi(n)$ holds. This set is said to be *defined by* the given formula $\varphi(n)$. For example, if $\varphi(n)$ is the formula $\exists m\,(m + m = n)$, then this instance of the comprehension scheme asserts the existence of the set of even numbers.

In the comprehension scheme, $\varphi(n)$ may contain free variables in addition to $n$. These free variables may be referred to as *parameters* of this instance of the comprehension scheme. Such terminology is in harmony

with definition I.2.3 and the discussion following it. For example, taking $\varphi(n)$ to be the formula $n \notin Y$, we have an instance of comprehension,

$$\forall Y\, \exists X\, \forall n\, (n \in X \leftrightarrow n \notin Y),$$

asserting that for any given set $Y$ there exists a set $X =$ the complement of $Y$. Here the variable $Y$ plays the role of a parameter.

Note that an $L_2$-structure $M$ satisfies I.2.4(iii), the comprehension scheme, if and only if $\mathcal{S}_M$ contains all subsets of $|M|$ which are definable over $M$ allowing parameters from $|M| \cup \mathcal{S}_M$. In particular, the comprehension scheme is valid in the intended model. Note also that the basic axioms I.2.4(i) and the induction axiom I.2.4(ii) are valid in any $\omega$-model. In fact, any $\omega$-model satisfies the full *second order induction scheme*, i.e., the universal closure of

$$(\varphi(0) \wedge \forall n\, (\varphi(n) \to \varphi(n+1))) \to \forall n\, \varphi(n),$$

where $\varphi(n)$ is any formula of $L_2$. In addition, the second order induction scheme is valid in any model of I.2.4(ii) plus I.2.4(iii).

By *second order arithmetic* we mean the formal system in the language $L_2$ consisting of the axioms of second order arithmetic, together with all formulas of $L_2$ which are deducible from those axioms by means of the usual logical axioms and rules of inference. The formal system of second order arithmetic is also known as $Z_2$, for obvious reasons, or $\Pi^1_\infty$-$CA_0$, for reasons which will become clear in §I.5.

In general, a *formal system* is defined by specifying a language and some axioms. Any formula of the given language which is logically deducible from the given axioms is said to be a *theorem* of the given formal system. At all times we assume the usual logical rules and axioms, including equality axioms and the law of the excluded middle.

This book will be largely concerned with certain specific subsystems of second order arithmetic and the formalization of ordinary mathematics within those systems. By a *subsystem of* $Z_2$ we mean of course a formal system in the language $L_2$ each of whose axioms is a theorem of $Z_2$. When introducing a new subsystem of $Z_2$, we shall specify the axioms of the system by writing down some formulas of $L_2$. The axioms are then taken to be the universal closures of those formulas.

If $T$ is any subsystem of $Z_2$, a *model of* $T$ is any $L_2$-structure satisfying the axioms of $T$. By Gödel's completeness theorem applied to the two-sorted language $L_2$, we have the following important principle: A given $L_2$-sentence $\sigma$ is a theorem of $T$ if and only if all models of $T$ satisfy $\sigma$. An *$\omega$-model of* $T$ is of course any $\omega$-model which satisfies the axioms of $T$, and similarly a *$\beta$-model of* $T$ is any $\beta$-model satisfying the axioms of $T$. Chapters VII, VIII, and IX of this book constitute a thorough

study of models of subsystems of $Z_2$. Chapter VII is concerned with $\beta$-models, chapter VIII is concerned with $\omega$-models other than $\beta$-models, and chapter IX is concerned with models other than $\omega$-models.

All of the subsystems of $Z_2$ which we shall consider consist of the basic axioms I.2.4(i), the induction axiom I.2.4(ii), and some set existence axioms. The various subsystems will differ from each other only with respect to their set existence axioms. Recall from §I.1 that our Main Question concerns the role of set existence axioms in ordinary mathematics. Thus, a principal theme of this book will be the formal development of specific portions of ordinary mathematics within specific subsystems of $Z_2$. We shall see that subsystems of $Z_2$ provide a setting in which the Main Question can be investigated in a precise and fruitful way. Although $Z_2$ has infinitely many subsystems, it will turn out that only a handful of them are useful in our study of the Main Question.

**Notes for §I.2.** The formal system $Z_2$ of second order arithmetic was introduced in Hilbert/Bernays [115] (in an equivalent form, using a somewhat different language and axioms). The development of a portion of ordinary mathematics within $Z_2$ is outlined in Supplement IV of Hilbert/Bernays [115]. The present book may be regarded as a continuation of the research begun by Hilbert and Bernays.

## I.3. The System $ACA_0$

The previous section contained generalities about subsystems of $Z_2$. The purpose of this section is to introduce a particular subsystem of $Z_2$ which is of central importance, namely $ACA_0$.

In our designation $ACA_0$, the acronym ACA stands for arithmetical comprehension axiom. This is because $ACA_0$ contains axioms asserting the existence of any set which is arithmetically definable from given sets (in a sense to be made precise below). The subscript 0 denotes restricted induction. This means that $ACA_0$ does not include the full second order induction scheme (as defined in §I.2). We assume only the induction axiom I.2.4(ii).

We now proceed to the definition of $ACA_0$.

DEFINITION I.3.1 (arithmetical formulas). A formula of $L_2$, or more generally a formula of $L_2(|M| \cup \mathcal{S}_M)$ where $M$ is any $L_2$-structure, is said to be *arithmetical* if it contains no set quantifiers, i.e., all of the quantifiers appearing in the formula are number quantifiers.

Note that arithmetical formulas of $L_2$ may contain free set variables, as well as free and bound number variables and number quantifiers. Arithmetical formulas of $L_2(|M| \cup \mathcal{S}_M)$ may additionally contain set parameters

and number parameters, i.e., constant symbols denoting fixed elements of $\mathcal{S}_M$ and $|M|$ respectively.

Examples of arithmetical formulas of $\mathrm{L}_2$ are

$$\forall n\,(n \in X \to \exists m\,(m + m = n)),$$

asserting that all elements of the set $X$ are even, and

$$\forall m\,\forall k\,(n = m \cdot k \to (m = 1 \vee k = 1)) \wedge n > 1 \wedge n \in X,$$

asserting that $n$ is a prime number and is an element of $X$. An example of a non-arithmetical formula is

$$\exists Y\,\forall n\,(n \in X \leftrightarrow \exists i\,\exists j\,(i \in Y \wedge j \in Y \wedge i + n = j))$$

asserting that $X$ is the set of differences of elements of some set $Y$.

DEFINITION I.3.2 (arithmetical comprehension). The *arithmetical comprehension scheme* is the restriction of the comprehension scheme I.2.4(iii) to arithmetical formulas $\varphi(n)$. Thus we have the universal closure of

$$\exists X\,\forall n\,(n \in X \leftrightarrow \varphi(n))$$

whenever $\varphi(n)$ is a formula of $\mathrm{L}_2$ which is arithmetical and in which $X$ does not occur freely. $\mathsf{ACA}_0$ is the subsystem of $\mathsf{Z}_2$ whose axioms are the arithmetical comprehension scheme, the induction axiom I.2.4(ii), and the basic axioms I.2.4(i).

Note that an $\mathrm{L}_2$-structure

$$M = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$

satisfies the arithmetical comprehension scheme if and only if $\mathcal{S}_M$ contains all subsets of $|M|$ which are definable over $M$ by arithmetical formulas with parameters from $|M| \cup \mathcal{S}_M$. Thus, a model of $\mathsf{ACA}_0$ is any such $\mathrm{L}_2$-structure which in addition satisfies the induction axiom and the basic axioms.

An easy consequence of the arithmetical comprehension scheme and the induction axiom is the *arithmetical induction scheme*:

$$(\varphi(0) \wedge \forall n\,(\varphi(n) \to \varphi(n + 1))) \to \forall n\,\varphi(n)$$

for all $\mathrm{L}_2$-formulas $\varphi(n)$ which are arithmetical. Thus any model of $\mathsf{ACA}_0$ is also a model of the arithmetical induction scheme. (Note however that $\mathsf{ACA}_0$ does not include the second order induction scheme, as defined in §I.2.)

REMARK I.3.3 (first order arithmetic). We wish to remark that there is a close relationship between $\mathsf{ACA}_0$ and first order arithmetic. Let $\mathrm{L}_1$ be the *language of first order arithmetic*, i.e., $\mathrm{L}_1$ is just $\mathrm{L}_2$ with the set variables omitted. *First order arithmetic* is the formal system $\mathsf{Z}_1$ whose language

is $L_1$ and whose axioms are the basic axioms I.2.4(i) plus the *first order induction scheme*:

$$(\varphi(0) \wedge \forall n\,(\varphi(n) \to \varphi(n+1))) \to \forall n\,\varphi(n)$$

for all $L_1$-formulas $\varphi(n)$. In the literature of mathematical logic, first order arithmetic is sometimes known as *Peano arithmetic*, PA. By the previous paragraph, every theorem of $Z_1$ is a theorem of $ACA_0$. In model-theoretic terms, this means that for any model $(|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$ of $ACA_0$, its first order part $(|M|, +_M, \cdot_M, 0_M, 1_M, <_M)$ is a model of $Z_1$. In §IX.1 we shall prove a converse to this result: Given a model

$$(|M|, +_M, \cdot_M, 0_M, 1_M, <_M) \tag{1}$$

of first order arithmetic, we can find $\mathcal{S}_M \subseteq P(|M|)$ such that

$$(|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$

is a model of $ACA_0$. (Namely, we can take $\mathcal{S}_M = \mathrm{Def}(M) =$ the set of all $A \subseteq |M|$ such that $A$ is definable over (1) allowing parameters from $|M|$.) It follows that, for any $L_1$-sentence $\sigma$, $\sigma$ is a theorem of $ACA_0$ if and only if $\sigma$ is a theorem of $Z_1$. In other words, $ACA_0$ is a *conservative extension* of first order arithmetic. This may also be expressed by saying that $Z_1$, or equivalently PA, is the *first order part* of $ACA_0$. For details, see §IX.1.

REMARK I.3.4 ($\omega$-models of $ACA_0$). Assuming familiarity with some basic concepts of recursive function theory, we can characterize the $\omega$-models of $ACA_0$ as follows. $\mathcal{S} \subseteq P(\omega)$ is an $\omega$-model of $ACA_0$ if and only if

(i) $\mathcal{S} \neq \emptyset$;
(ii) $A \in \mathcal{S}$ and $B \in \mathcal{S}$ imply $A \oplus B \in \mathcal{S}$;
(iii) $A \in \mathcal{S}$ and $B \leq_T A$ imply $B \in \mathcal{S}$;
(iv) $A \in \mathcal{S}$ implies $TJ(A) \in \mathcal{S}$.

(This result is proved in §VIII.1.)

Here $A \oplus B$ is the *recursive join* of $A$ and $B$, defined by

$$A \oplus B = \{2n : n \in A\} \cup \{2n+1 : n \in B\}.$$

$B \leq_T A$ means that $B$ is *Turing reducible* to $A$, i.e., $B$ is *recursive in* $A$, i.e., the characteristic function of $B$ is computable assuming an oracle for the characteristic function of $A$. $TJ(A)$ denotes the *Turing jump* of $A$, i.e., the complete recursively enumerable set relative to $A$.

In particular, $ACA_0$ has a minimum (i.e., unique smallest) $\omega$-model, namely

$$\mathrm{ARITH} = \{A \in P(\omega) : \exists n \in \omega\,(A \leq_T TJ(n, \emptyset))\},$$

where $TJ(n, X)$ is defined inductively by $TJ(0, X) = X$, $TJ(n+1, X) = TJ(TJ(n, X))$. More generally, given a set $B \in P(\omega)$, there is a unique smallest $\omega$-model of $ACA_0$ containing $B$, consisting of all sets which are

arithmetical in $B$. (For $A, B \in P(\omega)$, we say that $A$ is *arithmetical in* $B$ if $A \leq_{\mathrm{T}} \mathrm{TJ}(n, B)$ for some $n \in \omega$. This is equivalent to saying that $A$ is definable in some or any $\omega$-model $(\omega, \mathcal{S}, +, \cdot, 0, 1, <)$, $B \in \mathcal{S} \subseteq P(\omega)$, by an arithmetical formula with $B$ as a parameter.)

Models of $\mathsf{ACA}_0$ are discussed further in §§VIII.1, IX.1, and IX.4. The development of ordinary mathematics within $\mathsf{ACA}_0$ is discussed in §I.4 and in chapters II, III, and IV.

**Notes for §I.3.** By remark I.3.3, the system $\mathsf{ACA}_0$ is closely related to first order arithmetic. First order arithmetic is one of the best known and most studied formal systems in the literature of mathematical logic. See for instance Hilbert/Bernays [115], Mendelson [185, chapter 3], Takeuti [261, chapter 2], Shoenfield [222, chapter 8], Hájek/Pudlák [100], and Kaye [137]. By remark I.3.4, $\omega$-models of $\mathsf{ACA}_0$ are closely related to basic concepts of recursion theory such as relative recursiveness, the Turing jump operator, and the arithmetical hierarchy. For an introduction to these concepts, see for instance Rogers [208, chapters 13–15], Shoenfield [222, chapter 7], Cutland [43], or Lerman [161, chapters I–III].

## I.4. Mathematics within $\mathsf{ACA}_0$

The formal system $\mathsf{ACA}_0$ was introduced in the previous section. We now outline the development of certain portions of ordinary mathematics within $\mathsf{ACA}_0$. The material presented in this section will be restated and greatly refined and extended in chapters II, III, and IV. The present discussion is intended as a partial preview of those chapters.

If $X$ and $Y$ are set variables, we use $X = Y$ and $X \subseteq Y$ as abbreviations for the formulas $\forall n\,(n \in X \leftrightarrow n \in Y)$ and $\forall n\,(n \in X \rightarrow n \in Y)$ respectively.

Within $\mathsf{ACA}_0$, we define $\mathbb{N}$ to be the unique set $X$ such that $\forall n\,(n \in X)$. (The existence of this set follows from arithmetical comprehension applied to the formula $\varphi(n) \equiv n = n$.) Thus, in any model

$$M = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$

of $\mathsf{ACA}_0$, $\mathbb{N}$ denotes $|M|$, the set of natural numbers in the sense of $M$, and we have $|M| \in \mathcal{S}_M$. We shall distinguish between $\mathbb{N}$ and $\omega$, reserving $\omega$ to denote the set of natural numbers in the sense of "the real world," i.e., the metatheory in which we are working, whatever that metatheory might be.

Within $\mathsf{ACA}_0$, we define a *numerical pairing function* by

$$(m, n) = (m + n)^2 + m.$$

Within $\mathsf{ACA}_0$ we can prove that, for all $m, n, i, j \in \mathbb{N}$, $(m, n) = (i, j)$ if and only if $m = i$ and $n = j$. Moreover, using arithmetical comprehension,

we can prove that for all sets $X, Y \subseteq \mathbb{N}$, there exists a set $X \times Y \subseteq \mathbb{N}$ consisting of all $(m, n)$ such that $m \in X$ and $n \in Y$. In particular we have $\mathbb{N} \times \mathbb{N} \subseteq \mathbb{N}$.

For $X, Y \subseteq \mathbb{N}$, a *function* $f : X \to Y$ is defined to be a set $f \subseteq X \times Y$ such that for all $m \in X$ there is exactly one $n \in Y$ such that $(m, n) \in f$. For $m \in X$, $f(m)$ is defined to be the unique $n$ such that $(m, n) \in f$. The usual properties of such functions can be proved in $\mathsf{ACA}_0$. In particular, we have *primitive recursion*. This means that, given $f : X \to Y$ and $g : \mathbb{N} \times X \times Y \to Y$, there is a unique $h : \mathbb{N} \times X \to Y$ defined by $h(0, m) = f(m)$, $h(n+1, m) = g(n, m, h(n, m))$ for all $n \in \mathbb{N}$ and $m \in X$. The existence of $h$ is proved by arithmetical comprehension, and the uniqueness of $h$ is proved by arithmetical induction. (For details, see §II.3.) In particular, we have the *exponential function* $\exp(m, n) = m^n$, defined by $m^0 = 1$, $m^{n+1} = m^n \cdot m$ for all $m, n \in \mathbb{N}$. The usual properties of the exponential function can be proved in $\mathsf{ACA}_0$.

In developing ordinary mathematics within $\mathsf{ACA}_0$, our first major task is to set up the *number systems*, i.e., the natural numbers, the integers, the rational number system, and the real number system.

The natural number system is essentially already given to us by the language and axioms of $\mathsf{ACA}_0$. Thus, within $\mathsf{ACA}_0$, a *natural number* is defined to be an element of $\mathbb{N}$, and the *natural number system* is defined to be the structure $\mathbb{N}, +_{\mathbb{N}}, \cdot_{\mathbb{N}}, 0_{\mathbb{N}}, 1_{\mathbb{N}}, <_{\mathbb{N}}, =_{\mathbb{N}}$, where $+_{\mathbb{N}} : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ is defined by $m +_{\mathbb{N}} n = m + n$, etc. (Thus for instance $+_{\mathbb{N}}$ is the set of triples $((m, n), k) \in (\mathbb{N} \times \mathbb{N}) \times \mathbb{N}$ such that $m + n = k$. The existence of this set follows from arithmetical comprehension.) This means that, when we are working within any particular model $M = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$ of $\mathsf{ACA}_0$, a natural number is any element of $|M|$, and the role of the natural number system is played by $|M|, +_M, \cdot_M, 0_M, 1_M, <_M, =_M$. (Here $=_M$ is the identity relation on $|M|$.)

Basic properties of the natural number system, such as uniqueness of prime power decomposition, can be proved in $\mathsf{ACA}_0$ using arithmetical induction. (Here one can follow the usual development within first order arithmetic, as presented in textbooks of mathematical logic. Alternatively, see chapter II.)

In order to define the set $\mathbb{Z}$ of *integers* within (any model of) $\mathsf{ACA}_0$, we first use arithmetical comprehension to prove the existence of an equivalence relation $\equiv_{\mathbb{Z}} \subseteq (\mathbb{N} \times \mathbb{N}) \times (\mathbb{N} \times \mathbb{N})$ defined by $(m, n) \equiv_{\mathbb{Z}} (i, j)$ if and only if $m + j = n + i$. We then use arithmetical comprehension again, this time with $\equiv_{\mathbb{Z}}$ as a parameter, to prove the existence of the set $\mathbb{Z}$ consisting of all $(m, n) \in \mathbb{N} \times \mathbb{N}$ such that that $(m, n)$ is the minimum element of its equivalence class with respect to $\equiv_{\mathbb{Z}}$. (Here minimality is taken with respect to $<_{\mathbb{N}}$, using the fact that $\mathbb{N} \times \mathbb{N}$ is a subset of $\mathbb{N}$. Thus $\mathbb{Z}$ consists of one element of each $\equiv_{\mathbb{Z}}$-equivalence class.) Define $+_{\mathbb{Z}} : \mathbb{Z} \times \mathbb{Z} \to \mathbb{Z}$ by letting $(m, n) +_{\mathbb{Z}} (i, j)$ be the unique element

of $\mathbb{Z}$ such that $(m,n) +_{\mathbb{Z}} (i,j) \equiv_{\mathbb{Z}} (m+i, n+j)$. Here again arithmetical comprehension is used to prove the existence of $+_{\mathbb{Z}}$. Similarly, define $-_{\mathbb{Z}}\colon \mathbb{Z} \to \mathbb{Z}$ by $-_{\mathbb{Z}}(m,n) \equiv_{\mathbb{Z}} (n,m)$, and define $\cdot_{\mathbb{Z}}\colon \mathbb{Z} \times \mathbb{Z} \to \mathbb{Z}$ by $(m,n) \cdot_{\mathbb{Z}} (i,j) \equiv_{\mathbb{Z}} (mi+nj, mj+ni)$. Let $0_{\mathbb{Z}} = (0,0)$ and $1_{\mathbb{Z}} = (1,0)$. Define a relation $<_{\mathbb{Z}} \subseteq \mathbb{Z} \times \mathbb{Z}$ by letting $(m,n) <_{\mathbb{Z}} (i,j)$ if and only if $m + j < n + i$. Finally, let $=_{\mathbb{Z}}$ be the identity relation on $\mathbb{Z}$. This completes our definition of the system of integers within $\mathsf{ACA}_0$. We can prove within $\mathsf{ACA}_0$ that the system $\mathbb{Z}, +_{\mathbb{Z}}, -_{\mathbb{Z}}, \cdot_{\mathbb{Z}}, 0_{\mathbb{Z}}, 1_{\mathbb{Z}}, <_{\mathbb{Z}}, =_{\mathbb{Z}}$ has the usual properties of an ordered integral domain, the Euclidean property, etc.

In a similar manner, we can define within $\mathsf{ACA}_0$ the set of *rational numbers*, $\mathbb{Q}$. Let $\mathbb{Z}^+ = \{a \in \mathbb{Z}\colon 0 <_{\mathbb{Z}} a\}$ be the set of positive integers, and let $\equiv_{\mathbb{Q}}$ be the equivalence relation on $\mathbb{Z} \times \mathbb{Z}^+$ defined by $(a,b) \equiv_{\mathbb{Q}} (c,d)$ if and only if $a \cdot_{\mathbb{Z}} d = b \cdot_{\mathbb{Z}} c$. Then $\mathbb{Q}$ is defined to be the set of all $(a,b) \in \mathbb{Z} \times \mathbb{Z}^+$ such that $(a,b)$ is the $<_{\mathbb{N}}$-minimum element of its $\equiv_{\mathbb{Q}}$-equivalence class. Operations $+_{\mathbb{Q}}, -_{\mathbb{Q}}, \cdot_{\mathbb{Q}}$ on $\mathbb{Q}$ are defined by $(a,b) +_{\mathbb{Q}} (c,d) \equiv_{\mathbb{Q}} (a \cdot_{\mathbb{Z}} d +_{\mathbb{Z}} b \cdot_{\mathbb{Z}} c, b \cdot_{\mathbb{Z}} d)$, $-_{\mathbb{Q}}(a,b) \equiv_{\mathbb{Q}} (-_{\mathbb{Z}} a, b)$, and $(a,b) \cdot_{\mathbb{Q}} (c,d) \equiv_{\mathbb{Q}} (a \cdot_{\mathbb{Z}} c, b \cdot_{\mathbb{Z}} d)$. We let $0_{\mathbb{Q}} \equiv_{\mathbb{Q}} (0_{\mathbb{Z}}, 1_{\mathbb{Z}})$ and $1_{\mathbb{Q}} \equiv_{\mathbb{Q}} (1_{\mathbb{Z}}, 1_{\mathbb{Z}})$, and we define a binary relation $<_{\mathbb{Q}}$ on $\mathbb{Q}$ by letting $(a,b) <_{\mathbb{Q}} (c,d)$ if and only if $a \cdot_{\mathbb{Z}} d <_{\mathbb{Z}} b \cdot_{\mathbb{Z}} c$. Finally $=_{\mathbb{Q}}$ is the identity relation on $\mathbb{Q}$. We can then prove within $\mathsf{ACA}_0$ that the rational number system $\mathbb{Q}, +_{\mathbb{Q}}, -_{\mathbb{Q}}, \cdot_{\mathbb{Q}}, 0_{\mathbb{Q}}, 1_{\mathbb{Q}}, <_{\mathbb{Q}}, =_{\mathbb{Q}}$ has the usual properties of an ordered field, etc.

We make the usual identifications whereby $\mathbb{N}$ is regarded as a subset of $\mathbb{Z}$ and $\mathbb{Z}$ is regarded as a subset of $\mathbb{Q}$. (Namely $m \in \mathbb{N}$ is identified with $(m,0) \in \mathbb{Z}$, and $a \in \mathbb{Z}$ is identified with $(a, 1_{\mathbb{Z}}) \in \mathbb{Q}$.) We use $+$ ambiguously to denote $+_{\mathbb{N}}$, $+_{\mathbb{Z}}$, or $+_{\mathbb{Q}}$ and similarly for $-, \cdot, 0, 1, <$. For $q, r \in \mathbb{Q}$ we write $q - r = q + (-r)$, and if $r \neq 0$, $q/r =$ the unique $q' \in \mathbb{Q}$ such that $q = q' \cdot r$. The function $\exp(q,a) = q^a$ for $q \in \mathbb{Q} \setminus \{0\}$ and $a \in \mathbb{Z}$ is obtained by primitive recursion in the obvious way. The *absolute value* function $|\,|\colon \mathbb{Q} \to \mathbb{Q}$ is defined by $|q| = q$ if $q \geq 0$, $-q$ otherwise.

REMARK I.4.1. The idea behind our definitions of $\mathbb{Z}$ and $\mathbb{Q}$ within $\mathsf{ACA}_0$ is that $(m,n) \in \mathbb{N} \times \mathbb{N}$ corresponds to the integer $m - n$, while $(a,b) \in \mathbb{Z} \times \mathbb{Z}^+$ corresponds to the rational number $a/b$. Our treatment of $\mathbb{Z}$ and $\mathbb{Q}$ is similar to the classical Dedekind construction. The major difference is that we define $\mathbb{Z}$ and $\mathbb{Q}$ to be sets of representatives of the equivalence classes of $\equiv_{\mathbb{Z}}$ and $\equiv_{\mathbb{Q}}$ respectively, while Dedekind uses the equivalence classes themselves. Our reason for using representatives is that we are limited to the language of second order arithmetic, while Dedekind was working in a richer set-theoretic context.

A *sequence of rational numbers* is defined to be a function $f : \mathbb{N} \to \mathbb{Q}$. We denote such a sequence as $\langle q_n\colon n \in \mathbb{N}\rangle$, or simply $\langle q_n\rangle$, where $q_n = f(n)$. Similarly, a *double sequence of rational numbers* is a function $f : \mathbb{N} \times \mathbb{N} \to \mathbb{Q}$, denoted $\langle q_{mn}\colon m,n \in \mathbb{N}\rangle$ or simply $\langle q_{mn}\rangle$, where $q_{mn} = f(m,n)$.

DEFINITION I.4.2 (real numbers). Within $\mathsf{ACA}_0$, a *real number* is defined to be a Cauchy sequence of rational numbers, i.e., a sequence of rational numbers $x = \langle q_n : n \in \mathbb{N} \rangle$ such that

$$\forall \epsilon \, (\epsilon > 0 \to \exists m \, \forall n \, (m < n \to |q_m - q_n| < \epsilon)).$$

(But see remark I.4.4 below.) Here $\epsilon$ ranges over $\mathbb{Q}$. If $x = \langle q_n \rangle$ and $y = \langle q'_n \rangle$ are real numbers, we write $x =_{\mathbb{R}} y$ to mean that $\lim_n |q_n - q'_n| = 0$, i.e.,

$$\forall \epsilon \, (\epsilon > 0 \to \exists m \, \forall n \, (m < n \to |q_n - q'_n| < \epsilon)),$$

and we write $x <_{\mathbb{R}} y$ to mean that

$$\exists \epsilon \, (\epsilon > 0 \wedge \exists m \, \forall n \, (m < n \to q_n + \epsilon < q'_n)).$$

Also $x +_{\mathbb{R}} y = \langle q_n + q'_n \rangle$, $x \cdot_{\mathbb{R}} y = \langle q_n \cdot q'_n \rangle$, $-_{\mathbb{R}} x = \langle -q_n \rangle$, $0_{\mathbb{R}} = \langle 0 \rangle$, $1_{\mathbb{R}} = \langle 1 \rangle$.

Informally, we use $\mathbb{R}$ to denote the set of all real numbers. Thus $x \in \mathbb{R}$ means that $x$ is a real number. (Formally, we cannot speak of the set $\mathbb{R}$ within the language of second order arithmetic, since it is a set of sets.) We shall usually omit the subscript $\mathbb{R}$ in $+_{\mathbb{R}}, -_{\mathbb{R}}, \cdot_{\mathbb{R}}, 0_{\mathbb{R}}, 1_{\mathbb{R}}, <_{\mathbb{R}}, =_{\mathbb{R}}$. Thus the *real number system* consists of $\mathbb{R}, +, -, \cdot, 0, 1, <, =$. We shall sometimes identify a rational number $q \in \mathbb{Q}$ with the corresponding real number $x_q = \langle q \rangle$.

REMARK I.4.3. Note that we have not attempted to select elements of the $=_{\mathbb{R}}$-equivalence classes. The reason is that there is no convenient way to do so in $\mathsf{ACA}_0$. Instead, we must accustom ourselves to the fact that $=$ on $\mathbb{R}$ (i.e., $=_{\mathbb{R}}$) is an equivalence relation other than the identity relation. This will not cause any serious difficulties.

REMARK I.4.4. The above definition of the real number system is similar but not identical to the one which we shall actually use in our detailed discussion of ordinary mathematics within $\mathsf{ACA}_0$, chapters II through IV. The reason for the discrepancy is that the above definition, while suitable for use in $\mathsf{ACA}_0$ and intuitively appealing, is not suitable for use in weaker systems such as $\mathsf{RCA}_0$. ($\mathsf{RCA}_0$ will be introduced in §§I.7 and I.8 below.) The definition used for the detailed development is slightly less natural, but it has the advantage of working smoothly in weaker systems. In any case, the two definitions are equivalent over $\mathsf{ACA}_0$, equivalent in the sense that the two versions of the real number system which they define can be proved in $\mathsf{ACA}_0$ to be isomorphic.

Within $\mathsf{ACA}_0$ one can prove that the real number system has the usual properties of an Archimedean ordered field, etc. The *complex numbers* can be introduced as usual as pairs of real numbers. Within $\mathsf{ACA}_0$, it is straightforward to carry out the proofs of all the basic results in real and

complex linear and polynomial algebra. For example, the fundamental theorem of algebra can be proved in $\mathsf{ACA}_0$.

A *sequence of real numbers* is defined to be a double sequence of rational numbers $\langle q_{mn} : m, n \in \mathbb{N} \rangle$ such that for each $m$, $\langle q_{mn} : n \in \mathbb{N} \rangle$ is a real number. Such a sequence of real numbers is denoted $\langle x_m : m \in \mathbb{N} \rangle$, where $x_m = \langle q_{mn} : n \in \mathbb{N} \rangle$. Within $\mathsf{ACA}_0$ we can prove that every bounded sequence of real numbers has a least upper bound. This is a very useful completeness property of the real number system. For instance, it implies that an infinite series of positive terms is convergent if and only if the finite partial sums are bounded. (Stronger completeness properties for the most part cannot be proved in $\mathsf{ACA}_0$.)

We now turn to abstract algebra within $\mathsf{ACA}_0$. Because of the restriction to the language of second order arithmetic, we cannot expect to obtain a good general theory of arbitrary (countable and uncountable) algebraic structures. However, we can develop *countable algebra*, i.e., the theory of countable algebraic structures, within $\mathsf{ACA}_0$.

For instance, a *countable commutative ring* is defined within $\mathsf{ACA}_0$ to be a structure $R, +_R, -_R, \cdot_R, 0_R, 1_R$, where $R \subseteq \mathbb{N}$, $+_R : R \times R \to R$, etc., and the usual commutative ring axioms are assumed. (We include $0 \neq 1$ among those axioms.) The subscript $R$ is usually omitted. (An example is the ring of integers, $\mathbb{Z}, +_{\mathbb{Z}}, -_{\mathbb{Z}}, \cdot_{\mathbb{Z}}, 0_{\mathbb{Z}}, 1_{\mathbb{Z}}$, which was introduced above.) An *ideal* in $R$ is a set $I \subseteq R$ such that $a \in I$ and $b \in I$ imply $a + b \in I$, $a \in I$ and $r \in R$ imply $a \cdot r \in I$, and $0 \in I$ and $1 \notin I$. We define an equivalence relation $=_I$ on $R$ by $r =_I s$ if and only if $r - s \in I$. We let $R/I$ be the set of $r \in R$ such that $r$ is the $<_{\mathbb{N}}$-minimum element of its equivalence class under $=_I$. Thus $R/I$ consists of one element of each $=_I$-equivalence class of elements of $R$. With the appropriate operations, $R/I$ becomes a countable commutative ring, the quotient ring of $R$ by $I$. The ideal $I$ is said to be *prime* if $R/I$ is an integral domain, and *maximal* if $R/I$ is a field. With these definitions, the countable case of many basic results of commutative algebra can be proved in $\mathsf{ACA}_0$. See §§III.5 and IV.6.

Other countable algebraic structures, e.g., countable groups, can be defined and discussed in a similar manner, within $\mathsf{ACA}_0$. Countable fields are discussed in §§II.9, IV.4 and IV.5, and countable vector spaces are discussed in §III.4. It turns out that part of the theory of countable Abelian groups can be developed in $\mathsf{ACA}_0$, but other parts of the theory require stronger systems. See §§III.6, V.7 and VI.4.

Next we indicate how some basic concepts and results of analysis and topology can be developed within $\mathsf{ACA}_0$.

DEFINITION I.4.5 (complete separable metric spaces). Within $\mathsf{ACA}_0$, a (code for a) *complete separable metric space* is a nonempty set $A \subseteq \mathbb{N}$ together with a function $d : A \times A \to \mathbb{R}$ satisfying $d(a, a) = 0$, $d(a, b) =$

$d(b,a) \geq 0$, and $d(a,c) \leq d(a,b) + d(b,c)$ for all $a, b, c \in A$. (Formally, $d$ is a sequence of real numbers, indexed by $A \times A$.) We define a *point of the complete separable metric space* $\widehat{A}$ to be a sequence $x = \langle a_n : n \in \mathbb{N} \rangle$, $a_n \in A$, satisfying

$$\forall \epsilon \, (\epsilon > 0 \to \exists m \, \forall n \, (m < n \to d(a_m, a_n) < \epsilon)).$$

The pseudometric $d$ is extended from $A$ to $\widehat{A}$ by

$$d(x,y) = \lim_n d(a_n, b_n)$$

where $x = \langle a_n : n \in \mathbb{N} \rangle$ and $y = \langle b_n : n \in \mathbb{N} \rangle$. We write $x = y$ if and only if $d(x,y) = 0$.

For example, $\mathbb{R} = \widehat{\mathbb{Q}}$ under the metric $d(q,q') = |q - q'|$.

The idea of the above definition is that a complete separable metric space $\widehat{A}$ is presented by specifying a countable dense set $A$ together with the restriction of the metric to $A$. Then $\widehat{A}$ is defined as the completion of $A$ under the restricted metric. Just as in the case of the real number system, several difficulties arise from the circumstance that $\mathsf{ACA}_0$ is formalized in the language of second order arithmetic. First, there is no variable or term that can denote the set of all points in $\widehat{A}$ (although we can use notations such as $x \in \widehat{A}$, meaning that $x$ is a point of $\widehat{A}$). Second, equality for points of $\widehat{A}$ is an equivalence relation other than the identity relation. These difficulties are minor and do not seriously affect the content of the mathematical development concerning complete separable metric spaces within $\mathsf{ACA}_0$. They only affect the outward form of that development. A more important limitation is that, in the language of second order arithmetic, we cannot speak at all about nonseparable metric spaces. This remark is related to our remarks in §I.1 about set-theoretic versus "ordinary" or non-set-theoretic mathematics.

DEFINITION I.4.6 (continuous functions). Within $\mathsf{ACA}_0$, if $\widehat{A}$ and $\widehat{B}$ are complete separable metric spaces, a (code for a) *continuous function* $\phi : \widehat{A} \to \widehat{B}$ is a set $\Phi \subseteq A \times \mathbb{Q}^+ \times B \times \mathbb{Q}^+$ satisfying the following coherence conditions:

1. $(a,r,b,s) \in \Phi$ and $(a,r,b',s') \in \Phi$ imply $d(b,b') < s + s'$;
2. $(a,r,b,s) \in \Phi$ and $d(b,b') + s < s'$ imply $(a,r,b',s') \in \Phi$;
3. $(a,r,b,s) \in \Phi$ and $d(a,a') + r' < r$ imply $(a',r',b,s) \in \Phi$.

Here $a'$ ranges over $A$, $b'$ ranges over $B$, and $r'$ and $s'$ range over

$$\mathbb{Q}^+ = \{q \in \mathbb{Q} : q > 0\},$$

the positive rational numbers. In addition we require: for all $x \in \widehat{A}$ and $\epsilon > 0$ there exists $(a,r,b,s) \in \Phi$ such that $d(a,x) < r$ and $s < \epsilon$.

We can prove in $\mathsf{ACA}_0$ that for all $x \in \widehat{A}$ there exists $y \in \widehat{B}$ such that $d(b,y) \leq s$ for all $(a,r,b,s) \in \Phi$ such that $d(a,x) < r$. This $y$ is unique

up to equality of points in $\widehat{B}$, and we define $\phi(x) = y$. It can be shown that $x = x'$ implies $\phi(x) = \phi(x')$.

The idea of the above definition is that $(a, r, b, s) \in \Phi$ is a *neighborhood condition* giving us a piece of information about the continuous function $\phi\colon \widehat{A} \to \widehat{B}$. Namely, $(a, r, b, s) \in \Phi$ tells us that for all $x \in \widehat{A}$, $d(x, a) < r$ implies $d(\phi(x), b) \leq s$. The code $\Phi$ consists of sufficiently many neighborhood conditions so as to determine $\phi(x) \in \widehat{B}$ for all $x \in \widehat{A}$.

Taking $\widehat{A} = \mathbb{R}^n$ and $\widehat{B} = \mathbb{R}$ in the above definition, we obtain a concept of continuous real-valued function of $n$ real variables. Using this, the theory of differential and integral equations, calculus of variations, etc., can be developed as usual, within $\mathsf{ACA}_0$. For instance, the Ascoli lemma can be proved in $\mathsf{ACA}_0$ and then used to obtain the Peano existence theorem for solutions of ordinary differential equations (see §§III.2 and IV.8).

DEFINITION I.4.7 (open sets). Within $\mathsf{ACA}_0$, let $\widehat{A}$ be a complete separable metric space. A (code for an) *open set* in $\widehat{A}$ is any set $U \subseteq A \times \mathbb{Q}^+$. For $x \in \widehat{A}$ we write $x \in U$ if and only if $d(x, a) < r$ for some $(a, r) \in U$.

The idea of definition I.4.7 is that $(a, r) \in A \times \mathbb{Q}^+$ is a code for a *neighborhood* or *basic open set* $\mathrm{B}(a, r)$ in $\widehat{A}$. Here $x \in \mathrm{B}(a, r)$ if and only if $d(a, x) < r$. An open set $U$ is then defined as a union of basic open sets.

With definitions I.4.6 and I.4.7, the usual proofs of fundamental topological results can be carried out within $\mathsf{ACA}_0$, for the case of complete separable metric spaces. For instance, the Baire category theorem and the Tietze extension theorem go through in this setting (see §§II.5, II.6, and II.7).

A *separable Banach space* is defined within $\mathsf{ACA}_0$ to be a complete separable metric space $\widehat{A}$ arising from a countable pseudonormed vector space $A$ over the rational field $\mathbb{Q}$. For example, let $A = \mathbb{Q}[x]$ be the ring of polynomials in one variable $x$ over $\mathbb{Q}$. With the metric

$$d(f, g) = \left[\int_0^1 |f(x) - g(x)|^p \, dx\right]^{1/p},$$

$1 \leq p < \infty$, we have $\widehat{A} = \mathrm{L}_p[0, 1]$. Similarly, with the metric

$$d(f, g) = \sup_{0 \leq x \leq 1} |f(x) - g(x)|,$$

we have $\widehat{A} = \mathrm{C}[0, 1]$. As suggested by these examples, the basic theory of separable Banach and Frechet spaces can be developed formally within $\mathsf{ACA}_0$. In particular, the Hahn/Banach theorem, the open mapping theorem, and the Banach/Steinhaus uniform boundedness principle can be proved in this setting (see §§II.10, IV.9, X.2).

REMARK I.4.8. As in remark I.4.4, the above definitions of complete separable metric space, continuous function, open set, and separable Banach space are not the ones which we shall actually use in our detailed development in chapters II, III, and IV. However, the two sets of definitions are equivalent in $\mathsf{ACA}_0$.

**Notes for §I.4.** The observation that a great deal of ordinary mathematics can be developed formally within a system something like $\mathsf{ACA}_0$ goes back to Weyl [274]; see also definition X.3.2. See also Takeuti [260] and Zahn [281].

## I.5. $\Pi^1_1$-$\mathsf{CA}_0$ and Stronger Systems

In this section we introduce $\Pi^1_1$-$\mathsf{CA}_0$ and some other subsystems of $\mathsf{Z}_2$. These systems are much stronger than $\mathsf{ACA}_0$.

DEFINITION I.5.1 ($\Pi^1_1$ formulas). A formula $\varphi$ is said to be $\Pi^1_1$ if it is of the form $\forall X\, \theta$, where $X$ is a set variable and $\theta$ is an arithmetical formula. A formula $\varphi$ is said to be $\Sigma^1_1$ if it is of the form $\exists X\, \theta$, where $X$ is a set variable and $\theta$ is an arithmetical formula.

More generally, for $0 \leq k \in \omega$, a formula $\varphi$ is said to be $\Pi^1_k$ if it is of the form

$$\forall X_1\, \exists X_2\, \forall X_3 \cdots X_k\, \theta,$$

where $X_1, \ldots, X_k$ are set variables and $\theta$ is an arithmetical formula. A formula $\varphi$ is said to be $\Sigma^1_k$ if it is of the form

$$\exists X_1\, \forall X_2\, \exists X_3 \cdots X_k\, \theta,$$

where $X_1, \ldots, X_k$ are set variables and $\theta$ is an arithmetical formula. In both cases, $\varphi$ consists of $k$ alternating set quantifiers followed by a formula with no set quantifiers. In the $\Pi^1_k$ case, the first set quantifier is universal, while in the $\Sigma^1_k$ case it is existential (assuming $k \geq 1$). Thus for instance a $\Pi^1_2$ formula is of the form $\forall X\, \exists Y\, \theta$, and a $\Sigma^1_2$ formula is of the form $\exists X\, \forall Y\, \theta$, where $\theta$ is arithmetical. A $\Pi^1_0$ or $\Sigma^1_0$ formula is the same thing as an arithmetical formula.

The equivalences $\neg\forall X\, \varphi \equiv \exists X\, \neg\varphi$, $\neg\exists X\, \varphi \equiv \forall X\, \neg\varphi$, and $\neg\neg\varphi \equiv \varphi$ imply that any $\Pi^1_k$ formula is logically equivalent to the negation of a $\Sigma^1_k$ formula, and vice versa. Moreover, using $\Pi^1_k$ (respectively $\Sigma^1_k$) to denote the class of formulas logically equivalent to a $\Pi^1_k$ formula (respectively a $\Sigma^1_k$ formula), we have

$$\Pi^1_k \cup \Sigma^1_k \subseteq \Pi^1_{k+1} \cap \Sigma^1_{k+1}$$

for all $k \in \omega$. (This is proved by introducing dummy quantifiers.)

The hierarchy of $L_2$-formulas $\Pi^1_k$, $k \in \omega$, is closely related to the projective hierarchy in descriptive set theory.

Definition I.5.2 ($\Pi^1_1$ and $\Pi^1_k$ comprehension). $\Pi^1_1$-$\mathsf{CA}_0$ is the subsystem of $\mathsf{Z}_2$ whose axioms are the basic axioms I.2.4(i), the induction axiom I.2.4(ii), and the comprehension scheme I.2.4(iii) restricted to $L_2$-formulas $\varphi(n)$ which are $\Pi^1_1$. Thus we have the universal closure of

$$\exists X \, \forall n \, (n \in X \leftrightarrow \varphi(n))$$

for all $\Pi^1_1$ formulas $\varphi(n)$ in which $X$ does not occur freely.

The systems $\Pi^1_k$-$\mathsf{CA}_0$, $k \in \omega$, are defined similarly, with $\Pi^1_k$ replacing $\Pi^1_1$. In particular $\Pi^1_0$-$\mathsf{CA}_0$ is just $\mathsf{ACA}_0$, and for all $k \in \omega$ we have

$$\Pi^1_k\text{-}\mathsf{CA}_0 \subseteq \Pi^1_{k+1}\text{-}\mathsf{CA}_0.$$

It is also clear that

$$\mathsf{Z}_2 = \bigcup_{k \in \omega} \Pi^1_k\text{-}\mathsf{CA}_0.$$

For this reason, $\mathsf{Z}_2$ is sometimes denoted $\Pi^1_\infty$-$\mathsf{CA}_0$.

It would be possible to introduce systems $\Sigma^1_k$-$\mathsf{CA}_0$, $k \in \omega$, but they would be superfluous, because a simple argument shows that $\Sigma^1_k$-$\mathsf{CA}_0$ and $\Pi^1_k$-$\mathsf{CA}_0$ are equivalent, i.e., they have the same theorems.

[Namely, given a $\Sigma^1_k$ formula $\varphi(n)$, there is a logically equivalent formula $\neg\psi(n)$ where $\psi(n)$ is $\Pi^1_k$. Reasoning within $\Pi^1_k$-$\mathsf{CA}_0$ and applying $\Pi^1_k$ comprehension, we see that there exists a set $Y$ such that

$$\forall n \, (n \in Y \leftrightarrow \psi(n)).$$

Applying arithmetical comprehension with $Y$ as a parameter, there exists a set $X$ such that

$$\forall n \, (n \in X \leftrightarrow n \notin Y).$$

Then clearly

$$\forall n \, (n \in X \leftrightarrow \varphi(n)).$$

This shows that all the axioms of $\Sigma^1_k$-$\mathsf{CA}_0$ are theorems of $\Pi^1_k$-$\mathsf{CA}_0$. The converse is proved similarly.]

We now discuss models of $\Pi^1_k$-$\mathsf{CA}_0$, $1 \leq k \leq \infty$.

As explained in §I.3 above, $\mathsf{ACA}_0$ has a minimum $\omega$-model, and this model is very natural from both the recursion-theoretic and the model-theoretic points of view. It is therefore reasonable to ask about minimum $\omega$-models of $\Pi^1_k$-$\mathsf{CA}_0$. It turns out that, for $1 \leq k \leq \infty$, there is no minimum (or even minimal) $\omega$-model of $\Pi^1_k$-$\mathsf{CA}_0$. These negative results will be proved in §VIII.6. However, we can obtain a positive result by considering $\beta$-models instead of $\omega$-models. The relevant definition is as follows.

DEFINITION I.5.3 ($\beta$-models). A *$\beta$-model* is an $\omega$-model $\mathcal{S} \subseteq P(\omega)$ with the following property. If $\sigma$ is any $\Pi^1_1$ or $\Sigma^1_1$ sentence with parameters from $\mathcal{S}$, then $(\omega, \mathcal{S}, +, \cdot, 0, 1, <)$ satisfies $\sigma$ if and only if the intended model

$$(\omega, P(\omega), +, \cdot, 0, 1, <)$$

satisfies $\sigma$.

If $T$ is any subsystem of $\mathsf{Z}_2$, a *$\beta$-model of $T$* is any $\beta$-model satisfying the axioms of $T$. Chapter VII is a thorough study of $\beta$-models of subsystems of $Z_2$.

REMARK I.5.4 ($\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$). For readers who are familiar with some basic concepts of hyperarithmetical theory, the $\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$ can be characterized as follows. $\mathcal{S} \subseteq P(\omega)$ is a $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$ if and only if

(i) $\mathcal{S} \neq \emptyset$;
(ii) $A \in \mathcal{S}$ and $B \in \mathcal{S}$ imply $A \oplus B \in \mathcal{S}$;
(iii) $A \in \mathcal{S}$ and $B \leq_{\mathrm{H}} A$ imply $B \in \mathcal{S}$;
(iv) $A \in \mathcal{S}$ implies $\mathrm{HJ}(A) \in \mathcal{S}$.

Here $B \leq_{\mathrm{H}} A$ means that $B$ is hyperarithmetical in $A$, and $\mathrm{HJ}(A)$ denotes the hyperjump of $A$. In particular, there is a minimum (i.e., unique smallest) $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$, namely

$$\{A \in P(\omega) \colon \exists n \in \omega\, A \leq_{\mathrm{H}} \mathrm{HJ}(n, \emptyset)\}$$

where $\mathrm{HJ}(0, X) = X$, $\mathrm{HJ}(n+1, X) = \mathrm{HJ}(\mathrm{HJ}(n, X))$. These results will be proved in §VII.1.

REMARK I.5.5 (minimum $\beta$-models of $\Pi^1_k$-$\mathsf{CA}_0$). More generally, for each $k$ in the range $1 \leq k \leq \infty$, it can be shown that there exists a minimum $\beta$-model of $\Pi^1_k$-$\mathsf{CA}_0$. These models can be described in terms of Gödel's theory of constructible sets. For any ordinal number $\alpha$, let $\mathrm{L}_\alpha$ be the $\alpha$th level of the constructible hierarchy. Then the minimum $\beta$-model of $\Pi^1_k$-$\mathsf{CA}_0$ is of the form $\mathrm{L}_\alpha \cap P(\omega)$, where $\alpha = \alpha_k$ is a countable ordinal number depending on $k$. Moreover, $\alpha_1 < \alpha_2 < \cdots < \alpha_\infty$, and the $\beta$-models $\mathrm{L}_{\alpha_k} \cap P(\omega)$, $1 \leq k \leq \infty$, are all distinct. (These results are proved in §§VII.5 and VII.7.) It follows that, for each $k$, $\Pi^1_{k+1}$-$\mathsf{CA}_0$ is properly stronger than $\Pi^1_k$-$\mathsf{CA}_0$.

The development of ordinary mathematics within $\Pi^1_1$-$\mathsf{CA}_0$ and stronger systems is discussed in §I.6 and in chapters V and VI. Models of $\Pi^1_1$-$\mathsf{CA}_0$ and some stronger systems, including but not limited to $\Pi^1_k$-$\mathsf{CA}_0$ for $k \geq 2$, are discussed in §§VII.1, VII.5, VII.6, VII.7, VIII.6, and IX.4. Our treatment of constructible sets is in §VII.4. Our treatment of hyperarithmetical theory is in §VIII.3.

**Notes for §I.5.** For an exposition of Gödel's theory of constructible sets, see any good textbook of axiomatic set theory, e.g., Jech [130].

## I.6. Mathematics within $\Pi^1_1$-CA$_0$

The system $\Pi^1_1$-CA$_0$ was introduced in the previous section. We now discuss the development of ordinary mathematics within $\Pi^1_1$-CA$_0$. The material presented here will be restated and greatly refined and expanded in chapters V and VI.

We have seen in §I.4 that a large part of ordinary mathematics can already be developed in ACA$_0$, a subsystem of $Z_2$ which is much weaker than $\Pi^1_1$-CA$_0$. However, there are certain exceptional theorems of ordinary mathematics which can be proved in $\Pi^1_1$-CA$_0$ but cannot be proved in ACA$_0$. The exceptional theorems come from several branches of mathematics including countable algebra, the topology of the real line, countable combinatorics, and classical descriptive set theory.

What many of these exceptional theorems have in common is that they directly or indirectly involve countable ordinal numbers. The relevant definition is as follows.

DEFINITION I.6.1 (countable ordinal numbers). Within ACA$_0$ we define a *countable linear ordering* to be a structure $A, <_A$, where $A \subseteq \mathbb{N}$ and $<_A \subseteq A \times A$ is an irreflexive linear ordering of $A$, i.e., $<_A$ is transitive and, for all $a, b \in A$, exactly one of $a = b$ or $a <_A b$ or $b <_A a$ holds. The countable linear ordering $A, <_A$ is called a *countable well ordering* if there is no sequence $\langle a_n : n \in \mathbb{N}\rangle$ of elements of $A$ such that $a_{n+1} <_A a_n$ for all $n \in \mathbb{N}$. We view a countable well ordering $A, <_A$ as a code for a countable ordinal number, $\alpha$, which is intuitively just the order type of $A, <_A$. Two countable well orderings $A, <_A$ and $B, <_B$ are said to encode the same countable ordinal number if and only if they are isomorphic. Two countable well orderings $A, <_A$ and $B, <_B$ are said to be *comparable* if they are isomorphic or if one of them is isomorphic to a proper initial segment of the other. (Letting $\alpha$ and $\beta$ be the corresponding countable ordinal numbers, this means that either $\alpha = \beta$ or $\alpha < \beta$ or $\beta < \alpha$.)

REMARK I.6.2. The fact that any two countable well orderings are comparable turns out to be provable in $\Pi^1_1$-CA$_0$ but not in ACA$_0$ (see theorem I.11.5.1 and §V.6). Thus $\Pi^1_1$-CA$_0$, but not ACA$_0$, is strong enough to develop a good theory of countable ordinal numbers. Because of this, $\Pi^1_1$-CA$_0$ is strong enough to prove several important theorems of ordinary mathematics which are not provable in ACA$_0$. We now present several examples of this phenomenon.

EXAMPLE I.6.3 (Ulm's theorem). Consider the well known structure theory for countable Abelian groups. Let $G, +_G, -_G, 0_G$ be a countable Abelian group. We say that $G$ is *divisible* if for all $a \in G$ and $n > 0$ there exists $b \in G$ such that $nb = a$. We say that $G$ is *reduced* if $G$ has no nontrivial divisible subgroup. Within $\Pi^1_1$-CA$_0$, but not within ACA$_0$, one can

prove that every countable Abelian group is the direct sum of a divisible group and a reduced group. Now assume that $G$ is a countable Abelian $p$-group. (This means that for every $a \in G$ there exists $n \in \mathbb{N}$ such that $p^n a = 0$. Here $p$ is a fixed prime number.) One defines a transfinite sequence of subgroups $G_0 = G$, $G_{\alpha+1} = pG_\alpha$, and for limit ordinals $\delta$, $G_\delta = \bigcap_{\alpha<\delta} G_\alpha$. Thus $G$ is reduced if and only if $G_\infty = 0$. The *Ulm invariants* of $G$ are the numbers $\dim(P_\alpha/P_{\alpha+1})$, where $P_\alpha = \{a \in G_\alpha : pa = 0\}$ and the dimension is taken over the integers modulo $p$. Each Ulm invariant is either a natural number or $\infty$. *Ulm's theorem* states that two countable reduced Abelian $p$-groups are isomorphic if and only if their Ulm invariants are the same. Using the theory of countable ordinal numbers which is available in $\Pi^1_1$-$\mathsf{CA}_0$, one can carry out the construction of the Ulm invariants and the usual proof of Ulm's theorem within $\Pi^1_1$-$\mathsf{CA}_0$. Thus Ulm's theorem is a result of classical algebra which can be proved in $\Pi^1_1$-$\mathsf{CA}_0$ but not in $\mathsf{ACA}_0$. More on this topic is in §§V.7 and VI.4.

EXAMPLE I.6.4 (the Cantor/Bendixson theorem). Next we consider a theorem concerning closed sets in $n$-dimensional Euclidean space. A *closed set* in $\mathbb{R}^n$ is defined to be the complement of an open set. (Open sets were discussed in definition I.4.7.)

If $C$ is a closed set in $\mathbb{R}^n$, an *isolated point of* $C$ is a point $x \in C$ such that $\{x\} = C \cap U$ for some open set $U$. Clearly $C$ has at most countably many isolated points. We say that $C$ is *perfect* if $C$ has no isolated points. For any closed set $C$, the *derived set* of $C$ is a closed set $C'$ consisting of all points of $C$ which are not isolated. Thus $C \setminus C'$ is countable, and $C' = C$ if and only if $C$ is perfect. Given a closed set $C$, the derived sequence of $C$ is a transfinite sequence of closed subsets of $C$, defined by $C_0 = C$, $C_{\alpha+1}$ = the derived set of $C_\alpha$, and for limit ordinals $\delta$, $C_\delta = \bigcap_{\alpha<\delta} C_\alpha$. Within $\Pi^1_1$-$\mathsf{CA}_0$ we can prove that for all countable ordinal numbers $\alpha$, the closed set $C_\alpha$ exists. Furthermore $C_{\beta+1} = C_\beta$ for some countable ordinal number $\beta$. In this case we clearly have $C_\beta = C_\alpha$ for all $\alpha > \beta$, so we write $C_\beta = C_\infty$. Clearly $C_\infty$ is a perfect closed set. In fact, $C_\infty$ can be characterized as the largest perfect closed subset of $C$, and $C_\infty$ is therefore known as the *perfect kernel* of $C$.

In summary, for any closed set $C$ we have $C = K \cup S$ where $K$ is a perfect closed set (namely $K = C_\infty$) and $S$ is a countable set (namely $S =$ the union of the sets $C_\alpha \setminus C_{\alpha+1}$ for all countable ordinal numbers $\alpha$). If $K$ happens to be the empty set, then $C$ is itself countable.

The fact that every closed set in $\mathbb{R}^n$ is the union of a perfect closed set and a countable set is known as the *Cantor/Bendixson theorem*. It can be shown that the Cantor/Bendixson theorem is provable in $\Pi^1_1$-$\mathsf{CA}_0$ but not in weaker systems such as $\mathsf{ACA}_0$. This example is particularly striking because, although the proof of the Cantor/Bendixson theorem uses countable ordinal numbers, the statement of the theorem does not mention them. For details see §§VI.1 and V.4.

The Cantor/Bendixson theorem also applies more generally, to complete separable metric spaces other than $\mathbb{R}^n$. An important special case is the Baire space $\mathbb{N}^{\mathbb{N}}$. Note that points of $\mathbb{N}^{\mathbb{N}}$ may be identified with functions $f : \mathbb{N} \to \mathbb{N}$. The Cantor/Bendixson theorem for $\mathbb{N}^{\mathbb{N}}$ is closely related to the analysis of trees:

DEFINITION I.6.5 (trees). Within ACA$_0$ we let

$$\text{Seq} = \mathbb{N}^{<\mathbb{N}} = \bigcup_{k\in\mathbb{N}} \mathbb{N}^k$$

denote the set of (codes for) finite sequences of natural numbers. For $\sigma, \tau \in \mathbb{N}^{<\mathbb{N}}$ there is $\sigma^\frown\tau \in \mathbb{N}^{<\mathbb{N}}$ which is the *concatenation*, $\sigma$ followed by $\tau$. A *tree* is a set $T \subseteq \mathbb{N}^{<\mathbb{N}}$ such that any initial segment of a sequence in $T$ belongs to $T$. A *path* or *infinite path* through $T$ is a function $f : \mathbb{N} \to \mathbb{N}$ such that for all $k \in \mathbb{N}$, the initial sequence

$$f[k] = \langle f(0), f(1), \ldots, f(k-1)\rangle$$

belongs to $T$. The set of paths through $T$ is denoted $[T]$. Thus $T$ may be viewed as a code for the closed set $[T] \subseteq \mathbb{N}^{\mathbb{N}}$. If $T$ has no infinite path, we say that $T$ is *well founded*. An *end node* of $T$ is a sequence $\tau \in T$ which has no proper extension in $T$.

DEFINITION I.6.6 (perfect trees). Two sequences in $\mathbb{N}^{<\mathbb{N}}$ are said to be *compatible* if they are equal or one is an initial segment of the other. Given a tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ and a sequence $\sigma \in T$, we denote by $T_\sigma$ the set of $\tau \in T$ such that $\sigma$ is compatible with $\tau$. Given a tree $T$, there is a *derived tree* $T' \subseteq T$ consisting of all $\sigma \in T$ such that $T_\sigma$ contains a pair of incompatible sequences. We say that $T$ is *perfect* if $T' = T$, i.e., every $\sigma \in T$ has a pair of incompatible extensions $\tau_1, \tau_2 \in T$.

Given a tree $T$, we may consider a transfinite sequence of trees defined by $T_0 = T$, $T_{\alpha+1} =$ the derived tree of $T_\alpha$, and for limit ordinals $\delta$, $T_\delta = \bigcap_{\alpha<\delta} T_\alpha$. We write $T_\infty = T_\beta$ where $\beta$ is an ordinal such that $T_\beta = T_{\beta+1}$. Thus $T_\infty$ is the largest perfect subtree of $T$. These notions concerning trees are analogous to example I.6.4 concerning closed sets. Indeed, the closed set $[T_\infty]$ is the perfect kernel of the closed set $[T]$ in the Baire space $\mathbb{N}^{\mathbb{N}}$. As in example I.6.4, it turns out that the existence of $T_\infty$ is provable in $\Pi^1_1$-CA$_0$ but not in weaker systems such as ACA$_0$. This result will be proved in §VI.1.

Turning to another topic in mathematics, we point out that $\Pi^1_1$-CA$_0$ is strong enough to prove many of the basic results of classical descriptive set theory. By *classical descriptive set theory* we mean the study of Borel and analytic sets in complete separable metric spaces. The relevant definitions within ACA$_0$ are as follows.

DEFINITION I.6.7 (Borel sets). Let $\widehat{A}$ be a complete separable metric space. A (code for a) *Borel set* $B$ in $\widehat{A}$ is defined to be a set $B \subseteq \mathbb{N}^{<\mathbb{N}}$ such that

(i) $B$ is a well founded tree;
(ii) for any end node $\langle m_0, m_1, \dots, m_k\rangle$ of $B$, we have $m_k = (a, r)$ for some $(a, r) \in A \times \mathbb{Q}^+$;
(iii) $B$ contains exactly one sequence $\langle m_0\rangle$ of length 1.

In particular, for each $a \in A$ and $r \in \mathbb{Q}^+$ there is a Borel code $\langle (a, r)\rangle$. We take $\langle (a, r)\rangle$ to be a code for the basic open neighborhood $\mathrm{B}(a, r)$ as in definition I.4.7. Thus for all points $x \in \widehat{A}$ we have, by definition, $x \in \mathrm{B}(a, r)$ if and only if $d(a, x) < r$. If $B$ is a Borel code which is not of the form $\langle (a, r)\rangle$, then for each $\langle m_0, n\rangle \in B$ we have another Borel code

$$B_n = \{\langle\rangle\} \cup \{\langle n\rangle^\frown \tau : \langle m_0, n\rangle^\frown \tau \in B\}.$$

We use transfinite recursion to define the notion of a point $x \in \widehat{A}$ belonging to (the Borel set coded by) $B$, in such a way that $x \in B$ if and only if either $m_0$ is odd and $x \in B_n$ for some $n$, or $m_0$ is even and $x \notin B_n$ for some $n$. This recursion can be carried out in $\Pi^1_1$-$\mathsf{CA}_0$; see §V.3.

Thus the Borel sets form a $\sigma$-algebra containing the basic open sets and closed under countable union, countable intersection, and complementation.

DEFINITION I.6.8 (analytic sets). Let $\widehat{A}$ be a complete separable metric space. A (code for an) *analytic set* $S \subseteq \widehat{A}$ is defined to be a (code for a) continuous function $\phi : \mathbb{N}^{\mathbb{N}} \to \widehat{A}$. We put $x \in S$ if and only if

$$\exists f\, (f \in \mathbb{N}^{\mathbb{N}} \wedge \phi(f) = x).$$

It can be proved in $\mathsf{ACA}_0$ that a set is analytic if and only if it is defined by a $\Sigma^1_1$ formula with parameters.

EXAMPLE I.6.9 (classical descriptive set theory). Within $\Pi^1_1$-$\mathsf{CA}_0$ we can emulate the standard proofs of some well known classical results on Borel and analytic sets. This is possible because $\Pi^1_1$-$\mathsf{CA}_0$ includes a good theory of countable well orderings and countable well founded trees. In particular Souslin's theorem ("a set $S$ is Borel if and only if $S$ and its complement are analytic"), Lusin's theorem ("any two disjoint analytic sets can be separated by a Borel set"), and Kondo's theorem (coanalytic uniformization) are provable in $\Pi^1_1$-$\mathsf{CA}_0$ but not in $\mathsf{ACA}_0$. For details, see §§V.3 and VI.2.

With the above examples, $\Pi^1_1$-$\mathsf{CA}_0$ emerges as being of considerable interest with respect to the development of ordinary mathematics. Other examples of ordinary mathematical theorems which are provable in $\Pi^1_1$-$\mathsf{CA}_0$ are: determinacy of open sets in $\mathbb{N}^{\mathbb{N}}$ (see §V.8), and the Ramsey property for open sets in $[\mathbb{N}]^{\mathbb{N}}$ (see §V.9). These theorems, like Ulm's

theorem and the Cantor/Bendixson theorem, are exceptional in that they are not provable in $\mathsf{ACA}_0$.

Remark I.6.10 (Friedman-style independence results). There are a small number of even more exceptional theorems which, for instance, are provable in ZFC (i.e., Zermelo/Fraenkel set theory with the axiom of choice) but not in full $\mathsf{Z}_2$. As an example, consider the following corollary, due to Friedman [71], of a theorem of Martin [177, 178]: Given a symmetric Borel set $B \subseteq I \times I$, $I = [0, 1]$, there exists a Borel function $\phi\colon I \to I$ such that the graph of $\phi$ is either included in or disjoint from $B$. Friedman [71] has shown that this result is not provable in $\mathsf{Z}_2$ or even in simple type theory. This is related to Friedman's earlier result [66, 71] that Borel determinacy is not provable in simple type theory. More results of this kind are in [72] and in the Friedman volume [102].

**Notes for §I.6.** Chapters V and VI of this book deal with the development of mathematics in $\Pi^1_1$-$\mathsf{CA}_0$. The crucial role of comparablility of countable well orderings (remark I.6.2) was pointed out by Friedman [62, chapter II] and Steel [256, chapter I]; recent refinements are due to Friedman/Hirst [74] and Shore [223]. The impredicative nature of the Cantor/Bendixson theorem and Ulm's theorem was noted by Kreisel [149] and Feferman [58], respectively. An up-to-date textbook of classical descriptive set theory is Kechris [138]. Friedman has discovered a number of mathematically natural statements whose proofs require strong set existence axioms; see the Friedman volume [102] and recent papers such as [73].

## I.7. The System $\mathsf{RCA}_0$

In this section we introduce $\mathsf{RCA}_0$, an important subsystem of $\mathsf{Z}_2$ which is much weaker than $\mathsf{ACA}_0$.

The acronym RCA stands for recursive comprehension axiom. This is because $\mathsf{RCA}_0$ contains axioms asserting the existence of any set $A$ which is recursive in given sets $B_1, \ldots, B_k$ (i.e., such that the characteristic function of $A$ is computable assuming oracles for the characteristic functions of $B_1, \ldots, B_k$). As in $\mathsf{ACA}_0$ and $\Pi^1_1$-$\mathsf{CA}_0$, the subscript 0 in $\mathsf{RCA}_0$ denotes restricted induction. The axioms of $\mathsf{RCA}_0$ include $\Sigma^0_1$ induction, a form of induction which is weaker than arithmetical induction (as defined in §I.3) but stronger than the induction axiom I.2.4(ii).

We now proceed to the definition of $\mathsf{RCA}_0$.

Let $n$ be a number variable, let $t$ be a numerical term not containing $n$, and let $\varphi$ be a formula of $\mathsf{L}_2$. We use the following abbreviations:

$$\forall n < t\, \varphi \equiv \forall n\, (n < t \to \varphi),$$
$$\exists n < t\, \varphi \equiv \exists n\, (n < t \wedge \varphi).$$

Thus $\forall n < t$ means "for all $n$ less than $t$", and $\exists n < t$ means "there exists $n$ less than $t$ such that". We may also write $\forall n \leq t$ instead of $\forall n < t + 1$, and $\exists n \leq t$ instead of $\exists n < t + 1$.

The expressions $\forall n < t$, $\forall n \leq t$, $\exists n < t$, $\exists n \leq t$ are called *bounded number quantifiers*, or simply *bounded quantifiers*. A *bounded quantifier formula* is a formula $\varphi$ such that all of the quantifiers occurring in $\varphi$ are bounded number quantifiers. Thus the bounded quantifier formulas are a subclass of the arithmetical formulas. Examples of bounded quantifier formulas are

$$\exists m \leq n\,(n = m + m),$$

asserting that $n$ is even, and

$$\forall m < 2n\,(m \in X \leftrightarrow \exists k < m\,(m = 2k + 1)),$$

asserting that the first $n$ elements of $X$ are $1, 3, 5, \ldots, 2n - 1$.

DEFINITION I.7.1 ($\Sigma^0_1$ and $\Pi^0_1$ formulas). An $L_2$-formula $\varphi$ is said to be $\Sigma^0_1$ if it is of the form $\exists m\,\theta$, where $m$ is a number variable and $\theta$ is a bounded quantifier formula. An $L_2$-formula $\varphi$ is said to be $\Pi^0_1$ if it is of the form $\forall m\,\theta$, where $m$ is a number variable and $\theta$ is a bounded quantifier formula.

It can be shown that $\Sigma^0_1$ formulas are closely related to the notion of relative recursive enumerability in recursion theory. Namely, for $A, B \in P(\omega)$, $A$ is recursively enumerable in $B$ if and only if $A$ is definable over some or any $\omega$-model $(\omega, \mathcal{S}, +, \cdot, 0, 1, <)$, $B \in \mathcal{S} \subseteq P(\omega)$, by a $\Sigma^0_1$ formula with $B$ as a parameter. (See also remarks I.3.4 and I.7.5.)

DEFINITION I.7.2 ($\Sigma^0_1$ induction). The $\Sigma^0_1$ *induction scheme*, $\Sigma^0_1$-IND, is the restriction of the second order induction scheme (as defined in §I.2) to $L_2$-formulas $\varphi(n)$ which are $\Sigma^0_1$. Thus we have the universal closure of

$$(\varphi(0) \wedge \forall n\,(\varphi(n) \rightarrow \varphi(n + 1))) \rightarrow \forall n\,\varphi(n)$$

where $\varphi(n)$ is any $\Sigma^0_1$ formula of $L_2$.

The $\Pi^0_1$ *induction scheme*, $\Pi^0_1$-IND, is defined similarly. It can be shown that $\Sigma^0_1$-IND and $\Pi^0_1$-IND are equivalent (in the presence of the basic axioms I.2.4(i)). This easy but useful result is proved in §II.3.

DEFINITION I.7.3 ($\Delta^0_1$ comprehension). The $\Delta^0_1$ *comprehension scheme* consists of (the universal closures of) all formulas of the form

$$\forall n\,(\varphi(n) \leftrightarrow \psi(n)) \rightarrow \exists X\,\forall n\,(n \in X \leftrightarrow \varphi(n)),$$

where $\varphi(n)$ is any $\Sigma^0_1$ formula, $\psi(n)$ is any $\Pi^0_1$ formula, $n$ is any number variable, and $X$ is a set variable which does not occur freely in $\varphi(n)$.

In the $\Delta^0_1$ comprehension scheme, note that $\varphi(n)$ and $\psi(n)$ may contain parameters, i.e., free set variables and free number variables in addition to $n$. Thus an $\mathrm{L}_2$-structure $M$ satisfies $\Delta^0_1$ comprehension if and only if $\mathcal{S}_M$ contains all subsets of $|M|$ which are both $\Sigma^0_1$ and $\Pi^0_1$ definable over $M$ allowing parameters from $|M| \cup \mathcal{S}_M$.

Definition I.7.4 (definition of $\mathsf{RCA}_0$). $\mathsf{RCA}_0$ is the subsystem of $\mathsf{Z}_2$ consisting of the basic axioms I.2.4(i), the $\Sigma^0_1$ induction scheme I.7.2, and the $\Delta^0_1$ comprehension scheme I.7.3.

Remark I.7.5 ($\omega$-models of $\mathsf{RCA}_0$). In remark I.3.4, we characterized the $\omega$-models of $\mathsf{ACA}_0$ in terms of recursion theory. We can characterize the $\omega$-models of $\mathsf{RCA}_0$ in similar terms, as follows. $\mathcal{S} \subseteq P(\omega)$ is an $\omega$-model of $\mathsf{RCA}_0$ if and only if

(i) $\mathcal{S} \neq \emptyset$;
(ii) $A \in \mathcal{S}$ and $B \in \mathcal{S}$ imply $A \oplus B \in \mathcal{S}$;
(iii) $A \in \mathcal{S}$ and $B \leq_{\mathrm{T}} A$ imply $B \in \mathcal{S}$.

(This result is proved in §VIII.1.) In particular, $\mathsf{RCA}_0$ has a minimum (i.e., unique smallest) $\omega$-model, namely

$$\mathrm{REC} = \{A \in P(\omega) \colon A \text{ is recursive}\}.$$

More generally, given a set $B \in P(\omega)$, there is a unique smallest $\omega$-model of $\mathsf{RCA}_0$ containing $B$, consisting of all sets $A \in P(\omega)$ which are recursive in $B$.

The system $\mathsf{RCA}_0$ plays two key roles in this book and in foundational studies generally. First, as we shall see in chapter II, the development of ordinary mathematics within $\mathsf{RCA}_0$ corresponds roughly to the positive content of what is known as "computable mathematics" or "recursive analysis". Thus $\mathsf{RCA}_0$ is a kind of formalized recursive mathematics. Second, $\mathsf{RCA}_0$ frequently plays the role of a weak base theory in Reverse Mathematics. Most of the results of Reverse Mathematics in chapters III, IV, V, and VI will be stated formally as theorems of $\mathsf{RCA}_0$.

Remark I.7.6 (first order part of $\mathsf{RCA}_0$). By remark I.3.3, the first order part of $\mathsf{ACA}_0$ is first order arithmetic, PA. In a similar vein, we can characterize the first order part of $\mathsf{RCA}_0$. Namely, let $\Sigma^0_1$-PA be PA with induction restricted to $\Sigma^0_1$ formulas. (Thus $\Sigma^0_1$-PA is a formal system whose language is $\mathrm{L}_1$ and whose axioms are the basic axioms I.2.4(i) plus the universal closure of

$$(\varphi(0) \wedge \forall n\,(\varphi(n) \to \varphi(n+1))) \to \forall n\,\varphi(n)$$

for any formula $\varphi(n)$ of $\mathrm{L}_1$ which is $\Sigma^0_1$.) Clearly the axioms of $\Sigma^0_1$-PA are included in those of $\mathsf{RCA}_0$. Conversely, given any model

$$(|M|, +_M, \cdot_M, 0_M, 1_M, <_M) \tag{2}$$

of $\Sigma^0_1$-PA, it can be shown that there exists $\mathcal{S}_M \subseteq P(|M|)$ such that

$$(|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$

is a model of $\mathsf{RCA}_0$. (Namely, we can take $\mathcal{S}_M = \Delta^0_1\text{-Def}(M) =$ the set of all $A \subseteq |M|$ such that $A$ is both $\Sigma^0_1$ and $\Pi^0_1$ definable over (2) allowing parameters from $|M|$.) It follows that, for any sentence $\sigma$ in the language of first order arithmetic, $\sigma$ is a theorem of $\mathsf{RCA}_0$ if and only if $\sigma$ is a theorem of $\Sigma^0_1$-PA. In other words, $\Sigma^0_1$-PA is the first order part of $\mathsf{RCA}_0$. (These results are proved in §IX.1.)

Models of $\mathsf{RCA}_0$ are discussed further in §§VIII.1, IX.1, IX.2, and IX.3. The development of ordinary mathematics within $\mathsf{RCA}_0$ is outlined in §I.8 and is discussed thoroughly in chapter II.

REMARK I.7.7 ($\Sigma^0_1$ comprehension). It would be possible to define a system $\Sigma^0_1$-$\mathsf{CA}_0$ consisting of the basic axioms I.2.4(i), the induction axiom I.2.4(ii), and the $\Sigma^0_1$ *comprehension scheme*, i.e., the universal closure of

$$\exists X\, \forall n\, (n \in X \leftrightarrow \varphi(n))$$

for all $\Sigma^0_1$ formulas $\varphi(n)$ of $\mathrm{L}_2$ in which $X$ does not occur freely. However, the introduction of $\Sigma^0_1$-$\mathsf{CA}_0$ as a distinct subsystem of $\mathsf{Z}_2$ is unnecessary, because it turns out that $\Sigma^0_1$-$\mathsf{CA}_0$ is equivalent to $\mathsf{ACA}_0$. This easy but important result will be proved in §III.1.

Generalizing the notion of $\Sigma^0_1$ and $\Pi^0_1$ formulas, we have:

DEFINITION I.7.8 ($\Sigma^0_k$ and $\Pi^0_k$ formulas). For $0 \leq k \in \omega$, an $\mathrm{L}_2$-formula $\varphi$ is said to be $\Sigma^0_k$ (respectively $\Pi^0_k$) if it is of the form

$$\exists n_1\, \forall n_2\, \exists n_3 \cdots n_k\, \theta$$

(respectively $\forall n_1 \exists n_2 \forall n_3 \cdots n_k\, \theta$), where $n_1, \ldots, n_k$ are number variables and $\theta$ is a bounded quantifier formula. In both cases, $\varphi$ consists of $k$ alternating unbounded number quantifiers followed by a formula containing only bounded number quantifiers. In the $\Sigma^0_k$ case, the first unbounded number quantifier is existential, while in the $\Pi^0_k$ case it is universal (assuming $k \geq 1$). Thus for instance a $\Pi^0_2$ formula is of the form $\forall m\, \exists n\, \theta$, where $\theta$ is a bounded quantifier formula. A $\Sigma^0_0$ or $\Pi^0_0$ formula is the same thing as a bounded quantifier formula.

Clearly any $\Sigma^0_k$ formula is logically equivalent to the negation of a $\Pi^0_k$ formula, and vice versa. Moreover, up to logical equivalence of formulas, we have $\Sigma^0_k \cup \Pi^0_k \subseteq \Sigma^0_{k+1} \cap \Pi^0_{k+1}$, for all $k \in \omega$.

REMARK I.7.9 (induction and comprehension schemes). Generalizing definition I.7.2, we can introduce induction schemes $\Sigma^i_k$-IND and $\Pi^i_k$-IND, for all $k \in \omega$ and $i \in \{0, 1\}$. Clearly $\Sigma^0_\infty$-IND $= \bigcup_{k\in\omega} \Sigma^0_k$-IND is equivalent to arithmetical induction, and $\Sigma^1_\infty$-IND $= \bigcup_{k\in\omega} \Sigma^1_k$-IND is equivalent to the full second order induction scheme. It can be shown that, for all

$k \in \omega$ and $i \in \{0,1\}$, $\Sigma^i_k$-IND is equivalent to $\Pi^i_k$-IND and is properly weaker than $\Sigma^i_{k+1}$-IND. As for comprehension schemes, it follows from remark I.7.7 that the systems $\Sigma^0_k$-$\mathsf{CA}_0$ and $\Pi^0_k$-$\mathsf{CA}_0$, $1 \leq k \in \omega$, are all equivalent to each other and to $\mathsf{ACA}_0$, i.e., $\Pi^1_0$-$\mathsf{CA}_0$. On the other hand, we have remarked in §I.5 that, for each $k \in \omega$, $\Pi^1_k$-$\mathsf{CA}_0$ is equivalent to $\Sigma^1_k$-$\mathsf{CA}_0$ and is properly weaker than $\Pi^1_{k+1}$-$\mathsf{CA}_0$. In chapter VII we shall introduce the systems $\Delta^1_k$-$\mathsf{CA}_0$, $1 \leq k \in \omega$, and we shall show that $\Delta^1_k$-$\mathsf{CA}_0$ is properly stronger than $\Pi^1_{k-1}$-$\mathsf{CA}_0$ and properly weaker than $\Pi^1_k$-$\mathsf{CA}_0$.

**Notes for §I.7.** In connection with remark I.7.5, note that the literature of recursion theory sometimes uses the term *Turing ideals* referring to what we call $\omega$-models of $\mathsf{RCA}_0$. See for instance Lerman [161, page 29]. The system $\mathsf{RCA}_0$ was first introduced by Friedman [69] (in an equivalent form, using a somewhat different language and axioms). The system $\Sigma^0_1$-PA was first studied by Parsons [201]. For a thorough discussion of $\Sigma^0_1$-PA and other subsystems of first order arithmetic, see Hájek/Pudlák [100] and Kaye [137].

## I.8. Mathematics within $\mathsf{RCA}_0$

In this section we sketch how some concepts and results of ordinary mathematics can be developed in $\mathsf{RCA}_0$. This portion of ordinary mathematics is roughly parallel to the positive content of recursive analysis and recursive algebra. We shall also give some recursive counterexamples showing that certain other theorems of ordinary mathematics are recursively false and hence, although provable in $\mathsf{ACA}_0$, cannot be proved in $\mathsf{RCA}_0$.

As already remarked in I.4.4 and I.4.8, the strictures of $\mathsf{RCA}_0$ require us to modify our definitions of "real number" and "point of a complete separable metric space". The needed modifications are as follows:

DEFINITION I.8.1 (partially replacing I.4.2). Within $\mathsf{RCA}_0$, a (code for a) *real number* $x \in \mathbb{R}$ is defined to be a sequence of rational numbers $x = \langle q_n : n \in \mathbb{N} \rangle$, $q_n \in \mathbb{Q}$, such that

$$\forall m \, \forall n \, (m < n \to |q_m - q_n| < 1/2^m).$$

For real numbers $x$ and $y$ we have $x =_{\mathbb{R}} y$ if and only if

$$\forall m \, (|q_m - q'_m| \leq 1/2^{m-1}),$$

and $x <_{\mathbb{R}} y$ if and only if

$$\exists m \, (q_m + 1/2^m < q'_m).$$

Note that with definition I.8.1 we now have that the predicate $x < y$ is $\Sigma^0_1$, and the predicates $x \leq y$ and $x = y$ are $\Pi^0_1$, for $x, y \in \mathbb{R}$. Thus real

number comparisons have become easier, and therein lies the superiority of I.8.1 over I.4.2 within $\mathsf{RCA}_0$.

DEFINITION I.8.2 (partially replacing I.4.5). Within $\mathsf{RCA}_0$, a (code for a) complete separable metric space is defined as in I.4.5. However, a (code for a) *point of the complete separable metric space* $\widehat{A}$ is now defined in $\mathsf{RCA}_0$ to be a sequence $x = \langle a_n : n \in \mathbb{N} \rangle$, $a_n \in A$, satisfying $\forall m \, \forall n \, (m < n \to d(a_m, a_n) < 1/2^m)$. The extension of $d$ to $\widehat{A}$ is as in I.4.5.

Under definition I.8.2, the predicate $d(x, y) < r$ for $x, y \in \widehat{A}$ and $r \in \mathbb{R}$ becomes $\Sigma^0_1$. This makes I.8.2 far more appropriate than I.4.5 for use in $\mathsf{RCA}_0$. We shall also need to modify slightly our earlier definitions of "continuous function" in I.4.6 and "open set" in I.4.7; the modified definitions will be presented in II.6.1 and II.5.6.

With these new definitions, the development of mathematics within $\mathsf{RCA}_0$ is broadly similar to the development within $\mathsf{ACA}_0$ as already outlined in §I.4 above. For the most part, $\Delta^0_1$ comprehension is an adequate substitute for arithmetical comprehension. Thus $\mathsf{RCA}_0$ is strong enough to prove basic results of real and complex linear and polynomial algebra, up to and including the fundamental theorem of algebra, and basic properties of countable algebraic structures and of continuous functions on complete separable metric spaces. Also within $\mathsf{RCA}_0$ we can introduce sequences of real numbers, sequences of continuous functions, and separable Banach spaces including examples such as $\mathrm{C}[0, 1]$ and $\mathrm{L}_p[0, 1]$, $1 \leq p < \infty$, just as in $\mathsf{ACA}_0$ (§I.4). This detailed development within $\mathsf{RCA}_0$ will be presented in chapter II.

In addition to basic results (e.g., the fact that the composition of two continuous functions is continuous), a number of nontrivial theorems are also provable in $\mathsf{RCA}_0$. We have:

THEOREM I.8.3 (mathematics in $\mathsf{RCA}_0$). *The following ordinary mathematical theorems are provable in* $\mathsf{RCA}_0$:

1. *the Baire category theorem* (§§II.4, II.5);
2. *the intermediate value theorem* (§II.6);
3. *Urysohn's lemma and the Tietze extension theorem for complete separable metric spaces* (§II.7);
4. *the soundness theorem and a version of Gödel's completeness theorem in mathematical logic* (§II.8);
5. *existence of an algebraic closure of a countable field* (§II.9);
6. *existence of a unique real closure of a countable ordered field* (§II.9);
7. *the Banach/Steinhaus uniform boundedness principle* (§II.10).

On the other hand, a phenomenon of great interest for us is that many well known and important mathematical theorems which are routinely provable in $\mathsf{ACA}_0$ turn out not to be provable at all in $\mathsf{RCA}_0$. We now present an example of this phenomenon.

Example I.8.4 (the Bolzano/Weierstraß theorem). Let us denote by BW the statement of the Bolzano/Weierstraß theorem: "Every bounded sequence of real numbers contains a convergent subsequence." It is straightforward to show that BW is provable in $\mathsf{ACA}_0$.

We claim that BW is not provable in $\mathsf{RCA}_0$.

To see this, consider the $\omega$-model REC consisting of all recursive subsets of $\omega$. We have seen in I.7.5 that REC is a model of $\mathsf{RCA}_0$. We shall now show that BW is false in REC.

We use some basic results of recursive function theory. Let $A$ be a recursively enumerable subset of $\omega$ which is not recursive. For instance, we may take $A = K = \{n\colon \{n\}(n) \text{ is defined}\}$. Let $f\colon \omega \to \omega$ be a one-to-one recursive function such that $A =$ the range of $f$. Define a bounded increasing sequence of rational numbers $a_k$, $k \in \omega$, by putting

$$a_k = \sum_{m=0}^{k} \frac{1}{2^{f(m)}}.$$

Clearly the sequence $\langle a_k \rangle_{k\in\omega}$, or more precisely its code, is recursive and hence is an element of REC. On the other hand, it can be shown that the real number

$$r = \sup_{k\in\omega} a_k = \sum_{m=0}^{\infty} \frac{1}{2^{f(m)}} = \sum_{n\in A} \frac{1}{2^n}$$

is not recursive, i.e. (any code of) $r$ is not an element of REC. One way to see this would be to note that the characteristic function of the nonrecursive set $A$ would be computable if we allowed (any code of) $r$ as a Turing oracle.

Thus the $\omega$-model REC satisfies "$\langle a_k \rangle_{k\in\mathbb{N}}$ is a bounded increasing sequence of rational numbers, and $\langle a_k \rangle_{k\in\mathbb{N}}$ has no least upper bound". In particular, REC satisfies "$\langle a_k \rangle_{k\in\mathbb{N}}$ is a bounded sequence of real numbers which has no convergent subsequence". Hence BW is false in the $\omega$-model REC. Hence BW is not provable in $\mathsf{RCA}_0$.

Remark I.8.5 (recursive counterexamples). There is an extensive literature of what is known as "recursive analysis" or "computable mathematics", i.e., the systematic development of portions of ordinary mathematics within the particular $\omega$-model REC. (See the notes at the end of this section.) This literature contains many so-called "recursive counterexamples", where methods of recursive function theory are used to show that particular mathematical theorems are false in REC. Such results are of great interest with respect to our Main Question, §I.1, because they imply that the set existence axioms of $\mathsf{RCA}_0$ are not strong enough to prove the mathematical theorems under consideration. We have already presented one such recursive counterexample, showing that the Bolzano/Weierstraß

theorem is false in REC, hence not provable in $\mathsf{RCA}_0$. Other recursive counterexamples will be presented below.

EXAMPLE I.8.6 (the Heine/Borel covering lemma). Let us denote by HB the statement of the Heine/Borel covering lemma: Every covering of the closed interval $[0,1]$ by a sequence of open intervals has a finite subcovering. Again HB is provable in $\mathsf{ACA}_0$. We shall exhibit a recursive counterexample showing that HB is false in REC, hence not provable in $\mathsf{RCA}_0$.

Consider the well known Cantor middle third set $C \subseteq [0,1]$ defined by

$$C = [0,1] \setminus ((1/3, 2/3) \cup (1/9, 2/9) \cup (7/9, 8/9) \cup \dots).$$

There is a well known obvious recursive homeomorphism $H : C \cong \{0,1\}^\omega$, where $\{0,1\}^\omega$ is the product of $\omega$ copies of the two-point discrete space $\{0,1\}$. Points $h \in \{0,1\}^\omega$ may be identified with functions $h : \omega \to \{0,1\}$. For each $\varepsilon \in \{0,1\}$ and $n \in \omega$, let $U_n^\varepsilon$ be the union of $2^n$ effectively chosen rational open intervals such that

$$H(U_n^\varepsilon \cap C) = \{h \in \{0,1\}^\omega : h(n) = \varepsilon\}.$$

For instance, corresponding to $\varepsilon = 0$ and $n = 2$ we could choose $U_2^0 = (-1, 1/18) \cup (1/6, 5/18) \cup (1/2, 13/18) \cup (5/6, 17/18)$.

Now let $A$, $B$ be a disjoint pair of recursively inseparable, recursively enumerable subsets of $\omega$. For instance, we could take $A = \{n : \{n\}(n) \simeq 0\}$ and $B = \{n : \{n\}(n) \simeq 1\}$. Since $A$ and $B$ are recursively inseparable, it follows that for any recursive point $h \in \{0,1\}^\omega$ we have either $h(n) = 0$ for some $n \in A$, or $h(n) = 1$ for some $n \in B$. Let $f, g : \omega \to \omega$ be recursive functions such that $A = \mathrm{rng}(f)$ and $B = \mathrm{rng}(g)$. Then $U^0_{f(m)}$, $U^1_{g(m)}$, $m \in \omega$, give a recursive sequence of rational open intervals which cover the recursive reals in $C$ but not all of $C$. Combining this with the middle third intervals $(1/3, 2/3)$, $(1/9, 2/9)$, $(7/9, 8/9)$, ..., we obtain a recursive sequence of rational open intervals which cover the recursive reals in $[0,1]$ but not all of $[0,1]$. Thus the $\omega$-model REC satisfies "there exists a sequence of rational open intervals which is a covering of $[0,1]$ but has no finite subcovering". Hence HB is false in REC. Hence HB is not provable in $\mathsf{RCA}_0$.

EXAMPLE I.8.7 (the maximum principle). Another ordinary mathematical theorem not provable in $\mathsf{RCA}_0$ is the maximum principle: Every continuous real-valued function on $[0,1]$ attains a supremum. To see this, let $C$, $f$, $g$, $U_n^\varepsilon$, $\varepsilon \in \{0,1\}$, $n \in \omega$ be as in I.8.6, and let $r$, $a_k$, $k \in \omega$ be as in I.8.4. It is straightforward to construct a recursive code $\Phi$ for a function $\phi$ such that REC satisfies "$\phi : C \to \mathbb{R}$ is continuous and, for all $x \in C$, $\phi(x) = a_k$ where $k =$ the least $m$ such that $x \in U^0_{f(m)} \cup U^1_{g(m)}$". Thus $\sup\{\phi(x) : x \in C \cap \mathrm{REC}\} = \sup_{k \in \omega} a_k = r$ is a nonrecursive real number, so REC satisfies "$\sup_{x \in C} \phi(x)$ does not exist". Since $0 < a_k < 2$

for all $k$, we actually have $\phi\colon C \to [0,2]$ in REC. Also, we can extend $\phi$ uniquely to a continuous function $\psi\colon [0,1] \to [0,2]$ which is linear on intervals disjoint from $C$. Thus REC satisfies "$\psi\colon [0,1] \to [0,2]$ is continuous and $\sup_{x\in C} \psi(x)$ does not exist". Hence the maximum principle is false in REC and therefore not provable in $\mathsf{RCA}_0$.

EXAMPLE I.8.8 (König's lemma). Recall our notion of tree as defined in I.6.5. A tree $T$ is said to be *finitely branching* if for each $\sigma \in T$ there are only finitely many $n$ such that $\sigma^\frown\langle n\rangle \in T$. *König's lemma* is the following statement: every infinite, finitely branching tree has an infinite path.

We claim that König's lemma is provable in $\mathsf{ACA}_0$. An outline of the argument within $\mathsf{ACA}_0$ is as follows. Let $T \subseteq \mathbb{N}^{<\mathbb{N}}$ be an infinite, finitely branching tree. By arithmetical comprehension, there is a subtree $T^* \subseteq T$ consisting of all $\sigma \in T$ such that $T_\sigma$ (see definition I.6.6) is infinite. Since $T$ is infinite, the empty sequence $\langle\rangle$ belongs to $T^*$. Moreover, by the pigeonhole principle, $T^*$ has no end nodes. Define $f\colon \mathbb{N} \to \mathbb{N}$ by primitive recursion by putting $f(m) =$ the least $n$ such that $f[m]^\frown\langle n\rangle \in T^*$, for all $m \in \mathbb{N}$. Then $f$ is a path through $T^*$, hence through $T$, Q.E.D.

We claim that König's lemma is not provable in $\mathsf{RCA}_0$. To see this, let $A$, $B$, $f$, $g$ be as in I.8.6. Let $\{0,1\}^{<\omega}$ be the full binary tree, i.e., the tree of finite sequences of 0's and 1's. Let $T$ be the set of all $\tau \in \{0,1\}^{<\omega}$ such that, if $k =$ the length of $\tau$, then for all $m, n < k$, $f(m) = n$ implies $\tau(n) = 1$, and $g(m) = n$ implies $\tau(n) = 0$. Note that $T$ is recursive. Moreover, $h \in \{0,1\}^\omega$ is a path through $T$ if and only if $h$ separates $A$ and $B$, i.e., $h(n) = 1$ for all $n \in A$ and $h(n) = 0$ for all $n \in B$. Thus $T$ is an infinite, recursive, finitely branching tree with no recursive path. Hence we have a recursive counterexample to König's lemma, showing that König's lemma is false in REC, hence not provable in $\mathsf{RCA}_0$.

The recursive counterexamples presented above show that, although $\mathsf{RCA}_0$ is able to accommodate a large and significant portion of ordinary mathematical practice, it is also subject to some severe limitations. We shall eventually see that, in order to prove ordinary mathematical theorems such as the Bolzano/Weierstraß theorem, the Heine/Borel covering lemma, the maximum principle, and König's lemma, it is necessary to pass to subsystems of $\mathsf{Z}_2$ that are considerably stronger than $\mathsf{RCA}_0$. This investigation will lead us to another important theme: Reverse Mathematics (§§I.9, I.10, I.11, I.12).

REMARK I.8.9 (constructive mathematics). In some respects, our formal development of ordinary mathematics within $\mathsf{RCA}_0$ resembles the practice of Bishop-style constructivism [20]. However, there are some substantial differences (see also the notes below):

1. The constructivists believe that mathematical objects are purely mental constructions, while we make no such assumption.

2. The meaning which the constructivists assign to the propositional connectives and quantifiers is incompatible with our classical interpretation.
3. The constructivists assume unrestricted induction on the natural numbers, while in $\mathsf{RCA}_0$ we assume only $\Sigma^0_1$ induction.
4. We always assume the law of the excluded middle, while the constructivists deny it.
5. The typical constructivist response to a nonconstructive mathematical theorem is to modify the theorem by adding hypotheses or "extra data". In contrast, our approach in this book is to analyze the provability of mathematical theorems as they stand, passing to stronger subsystems of $\mathsf{Z}_2$ if necessary. See also our discussion of Reverse Mathematics in §I.9.

**Notes for §I.8.** Some references on recursive and constructive mathematics are Aberth [2], Beeson [17], Bishop/Bridges [20], Demuth/Kučera [46], Mines/Richman/Ruitenburg [189], Pour-El/Richards [203], and Troelstra/van Dalen [268]. The relationship between Bishop-style constructivism and $\mathsf{RCA}_0$ is discussed in [78, §0]. Chapter II of this book is devoted to the development of mathematics within $\mathsf{RCA}_0$. Some earlier literature presenting some of this development in a less systematic manner is Simpson [236], Friedman/Simpson/Smith [78], Brown/Simpson [27].

## I.9. Reverse Mathematics

We begin this section with a quote from Aristotle.

> Reciprocation of premisses and conclusion is more frequent in mathematics, because mathematics takes definitions, but never an accident, for its premisses—a second characteristic distinguishing mathematical reasoning from dialectical disputations. Aristotle, *Posterior Analytics* [184, 78a10].

The purpose of this section is to introduce one of the major themes of this book: Reverse Mathematics.

In order to motivate Reverse Mathematics from a foundational standpoint, consider the Main Question as defined in §I.1, concerning the role of set existence axioms. In §§I.4 and I.6, we have sketched an approximate answer to the Main Question. Namely, we have suggested that most theorems of ordinary mathematics can be proved in $\mathsf{ACA}_0$, and that of the exceptions, most can be proved in $\Pi^1_1$-$\mathsf{CA}_0$.

Consider now the following sharpened form of the Main Question: *Given a theorem $\tau$ of ordinary mathematics, what is the weakest natural subsystem $S(\tau)$ of $\mathsf{Z}_2$ in which $\tau$ is provable*?

Surprisingly, it turns out that for many specific theorems $\tau$ this question has a precise and definitive answer. Furthermore, $S(\tau)$ often turns out to be one of five specific subsystems of $\mathsf{Z}_2$. For convenience we shall now list these systems as $S_1$, $S_2$, $S_3$, $S_4$ and $S_5$ in order of increasing ability to accommodate ordinary mathematical practice. The odd numbered systems $S_1$, $S_3$ and $S_5$ have already been introduced as $\mathsf{RCA}_0$, $\mathsf{ACA}_0$ and $\Pi^1_1$-$\mathsf{CA}_0$ respectively. The even numbered systems $S_2$ and $S_4$ are intermediate systems which will be introduced in §§I.10 and I.11 below.

Our method for establishing results of the form $S(\tau) = S_j$, $2 \leq j \leq 5$ is based on the following empirical phenomenon: "When the theorem is proved from the right axioms, the axioms can be proved from the theorem." (Friedman [68].) Specifically, let $\tau$ be an ordinary mathematical theorem which is not provable in the weak base theory $S_1 = \mathsf{RCA}_0$. Then very often, $\tau$ turns out to be equivalent to $S_j$ for some $j = 2, 3, 4$ or 5. The equivalence is provable in $S_i$ for some $i < j$, usually $i = 1$.

For example, let $\tau$ = BW = the Bolzano/Weierstraß theorem: every bounded sequence of real numbers has a convergent subsequence. We have seen in I.8.4 that BW is false in the $\omega$-model REC. An adaptation of that argument gives the following result:

Theorem I.9.1. BW *is equivalent to* $\mathsf{ACA}_0$, *the equivalence being provable in* $\mathsf{RCA}_0$.

Proof. Note first that $\mathsf{ACA}_0 = \mathsf{RCA}_0$ plus arithmetical comprehension. Thus the forward direction of our theorem is obtained by observing that the usual proof of BW goes through in $\mathsf{ACA}_0$, as already remarked in §I.4.

For the reverse direction (i.e., the converse), we reason within $\mathsf{RCA}_0$ and assume BW. We are trying to prove arithmetical comprehension. Recall that, by relativization, arithmetical comprehension is equivalent to $\Sigma^0_1$ comprehension (see remark I.7.7). So let $\varphi(n)$ be a $\Sigma^0_1$ formula, say $\varphi(n) \equiv \exists m\, \theta(m, n)$ where $\theta$ is a bounded quantifier formula. For each $k \in \mathbb{N}$ define

$$c_k = \sum \{2^{-n} \colon n < k \wedge (\exists m < k)\, \theta(m, n)\}.$$

Then $\langle c_k \colon k \in \mathbb{N}\rangle$ is a bounded increasing sequence of rational numbers. This sequence exists by $\Delta^0_1$ comprehension, which is available to us since we are working in $\mathsf{RCA}_0$. Now by BW the limit $c = \lim_k c_k$ exists. Then we have

$$\forall n\, (\varphi(n) \leftrightarrow \forall k\, (|c - c_k| < 2^{-n} \rightarrow (\exists m < k)\, \theta(m, n))).$$

This gives the equivalence of a $\Sigma^0_1$ formula with a $\Pi^0_1$ formula. Hence by $\Delta^0_1$ comprehension we conclude $\exists X\, \forall n\, (n \in X \leftrightarrow \varphi(n))$. This proves $\Sigma^0_1$ comprehension and hence arithmetical comprehension. □

REMARK I.9.2 (on Reverse Mathematics). Theorem I.9.1 implies that $S_3 = \mathsf{ACA}_0$ is the weakest natural subsystem of $\mathsf{Z}_2$ in which $\tau = \mathrm{BW}$ is provable. Thus, for this particular case involving the Bolzano/Weierstraß theorem, I.9.1 provides a definitive answer to our sharpened form of the Main Question.

Note that the proof of theorem I.9.1 involved the deduction of a set existence axiom (namely arithmetical comprehension) from an ordinary mathematical theorem (namely BW). This is the opposite of the usual pattern of ordinary mathematical practice, in which theorems are deduced from axioms. The deduction of axioms from theorems is known as *Reverse Mathematics*. Theorem I.9.1 illustrates how Reverse Mathematics is the key to obtaining precise answers for instances of the Main Question. This point will be discussed more fully in §I.12.

We shall now state a number of results, similar to I.9.1, showing that particular ordinary mathematical theorems are equivalent to the axioms needed to prove them. These Reverse Mathematics results with respect to $\mathsf{ACA}_0$ and $\Pi^1_1$-$\mathsf{CA}_0$ will be summarized in theorems I.9.3 and I.9.4 and proved in chapters III and VI, respectively.

THEOREM I.9.3 (Reverse Mathematics for $\mathsf{ACA}_0$). *Within* $\mathsf{RCA}_0$ *one can prove that* $\mathsf{ACA}_0$ *is equivalent to each of the following ordinary mathematical theorems*:

1. *Every bounded, or bounded increasing, sequence of real numbers has a least upper bound* (§III.2).
2. *The Bolzano/Weierstraß theorem*: *Every bounded sequence of real numbers, or of points in* $\mathbb{R}^n$, *has a convergent subsequence* (§III.2).
3. *Every sequence of points in a compact metric space has a convergent subsequence* (§III.2).
4. *The Ascoli lemma*: *Every bounded equicontinuous sequence of real-valued continuous functions on a bounded interval has a uniformly convergent subsequence* (§III.2).
5. *Every countable commutative ring has a maximal ideal* (§III.5).
6. *Every countable vector space over* $\mathbb{Q}$, *or over any countable field, has a basis* (§III.4).
7. *Every countable field* (*of characteristic* 0) *has a transcendence basis* (§III.4).
8. *Every countable Abelian group has a unique divisible closure* (§III.6).
9. *König's lemma*: *Every infinite, finitely branching tree has an infinite path* (§III.7).
10. *Ramsey's theorem for colorings of* $[\mathbb{N}]^3$, *or of* $[\mathbb{N}]^4$, $[\mathbb{N}]^5$, ... (§III.7).

THEOREM I.9.4 (Reverse Mathematics for $\Pi^1_1$-$\mathsf{CA}_0$). *Within* $\mathsf{RCA}_0$ *one can prove that* $\Pi^1_1$-$\mathsf{CA}_0$ *is equivalent to each of the following ordinary mathematical statements*:

1. *Every tree has a largest perfect subtree* (§VI.1).
2. *The Cantor/Bendixson theorem*: *Every closed subset of* $\mathbb{R}$, *or of any complete separable metric space, is the union of a countable set and a perfect set* (§VI.1).
3. *Every countable Abelian group is the direct sum of a divisible group and a reduced group* (§VI.4).
4. *Every difference of two open sets in the Baire space* $\mathbb{N}^{\mathbb{N}}$ *is determined* (§VI.5).
5. *Every* $\mathrm{G}_\delta$ *set in* $[\mathbb{N}]^{\mathbb{N}}$ *has the Ramsey property* (§VI.6).
6. *Silver's theorem*: *For every Borel* (*or coanalytic, or* $\mathrm{F}_\sigma$) *equivalence relation with uncountably many equivalence classes, there exists a nonempty perfect set of inequivalent elements* (§VI.3).

More Reverse Mathematics results will be stated in §§I.10 and I.11 and proved in chapters IV and V, respectively. The significance of Reverse Mathematics for our Main Question will be discussed in §I.12.

**Notes for §I.9.** Historically, Reverse Mathematics may be viewed as a spin-off of Friedman's work [65, 66, 71, 72, 73] attempting to demonstrate the necessary use of higher set theory in mathematical practice. The theme of Reverse Mathematics in the context of subsystems of $\mathsf{Z}_2$ first appeared in Steel's thesis [256, chapter I] (an outcome of Steel's reading of Friedman's thesis [62, chapter II] under Simpson's supervision [230]) and in Friedman [68, 69]; see also Simpson [238]. This theme was taken up by Simpson and his collaborators in numerous studies [236, 241, 76, 235, 234, 78, 79, 250, 243, 246, 245, 21, 27, 28, 280, 80, 113, 112, 247, 127, 128, 26, 93, 248] which established it as a subject. The slogan "Reverse Mathematics" was coined by Friedman during a special session of the American Mathematical Society organized by Simpson.

## I.10. The System $\mathsf{WKL}_0$

In this section we introduce $\mathsf{WKL}_0$, a subsystem of $\mathsf{Z}_2$ consisting of $\mathsf{RCA}_0$ plus a set existence axiom known as *weak König's lemma*. We shall see that, in the notation of §I.9, $\mathsf{WKL}_0 = S_2$ is intermediate between $\mathsf{RCA}_0 = S_1$ and $\mathsf{ACA}_0 = S_3$. We shall also state several results of Reverse Mathematics with respect to $\mathsf{WKL}_0$ (theorem I.10.3 below).

In order to motivate $\mathsf{WKL}_0$ in terms of foundations of mathematics, consider our Main Question (§I.1) as it applies to three specific theorems of ordinary mathematics: the Bolzano/Weierstraß theorem, the Heine/Borel covering lemma, the maximum principle. We have seen in I.8.4, I.8.6, I.8.7 that these three theorems are not provable in $\mathsf{RCA}_0$. However, we have definitively answered the Main Question only for the

Bolzano/Weierstraß theorem, not for the other two. We have seen in I.9.1 that Bolzano/Weierstraß is equivalent to $\mathsf{ACA}_0$ over $\mathsf{RCA}_0$.

It will turn out (theorem I.10.3) that the Heine/Borel covering lemma, the maximum principle, and many other ordinary mathematical theorems are equivalent to each other and to weak König's lemma, over $\mathsf{RCA}_0$. Thus $\mathsf{WKL}_0$ is the weakest natural subsystem of $\mathsf{Z}_2$ in which these ordinary mathematical theorems are provable. Thus $\mathsf{WKL}_0$ provides the answer to these instances of the Main Question.

It will also turn out that $\mathsf{WKL}_0$ is sufficiently strong to accommodate a large portion of mathematical practice, far beyond what is available in $\mathsf{RCA}_0$, including many of the best-known non-constructive theorems. This will become clear in chapter IV.

We now present the definition of $\mathsf{WKL}_0$.

DEFINITION I.10.1 (weak König's lemma). The following definitions are made within $\mathsf{RCA}_0$. We use $\{0,1\}^{<\mathbb{N}}$ or $2^{<\mathbb{N}}$ to denote the full binary tree, i.e., the set of (codes for) finite sequences of 0's and 1's. *Weak König's lemma* is the following statement: Every infinite subtree of $2^{<\mathbb{N}}$ has an infinite path. (Compare definition I.6.5 and example I.8.8.)

$\mathsf{WKL}_0$ is defined to be the subsystem of $\mathsf{Z}_2$ consisting of $\mathsf{RCA}_0$ plus weak König's lemma.

REMARK I.10.2 ($\omega$-models of $\mathsf{WKL}_0$). By example I.8.8, the $\omega$-model REC consisting of all recursive subsets of $\omega$ does not satisfy weak König's lemma. Hence REC is not a model of $\mathsf{WKL}_0$. Since REC is the minimum $\omega$-model of $\mathsf{RCA}_0$ (remark I.7.5), it follows that $\mathsf{RCA}_0$ is a proper subsystem of $\mathsf{WKL}_0$. In addition, I.8.8 implies that $\mathsf{WKL}_0$ is a subsystem of $\mathsf{ACA}_0$. That it is a proper subsystem is not so obvious, but we shall see this in §VIII.2, where it is shown for instance that REC is the intersection of all $\omega$-models of $\mathsf{WKL}_0$. Thus we have

$$\mathsf{RCA}_0 \subsetneqq \mathsf{WKL}_0 \subsetneqq \mathsf{ACA}_0$$

and there are $\omega$-models for the independence.

We now list several results of Reverse Mathematics with respect to $\mathsf{WKL}_0$. These results will be proved in chapter IV.

THEOREM I.10.3 (Reverse Mathematics for $\mathsf{WKL}_0$). *Within* $\mathsf{RCA}_0$ *one can prove that* $\mathsf{WKL}_0$ *is equivalent to each of the following ordinary mathematical statements*:

1. *The Heine/Borel covering lemma*: *Every covering of the closed interval* $[0,1]$ *by a sequence of open intervals has a finite subcovering* (§IV.1).
2. *Every covering of a compact metric space by a sequence of open sets has a finite subcovering* (§IV.1).
3. *Every continuous real-valued function on* $[0,1]$, *or on any compact metric space, is bounded* (§IV.2).

4. *Every continuous real-valued function on* $[0,1]$, *or on any compact metric space, is uniformly continuous* (§IV.2).
5. *Every continuous real-valued function on* $[0,1]$ *is Riemann integrable* (§IV.2).
6. *The maximum principle*: *Every continuous real-valued function on* $[0,1]$, *or on any compact metric space, has, or attains, a supremum* (§IV.2).
7. *The local existence theorem for solutions of* (*finite systems of*) *ordinary differential equations* (§IV.8).
8. *Gödel's completeness theorem*: *every finite, or countable, set of sentences in the predicate calculus has a countable model* (§IV.3).
9. *Every countable commutative ring has a prime ideal* (§IV.6).
10. *Every countable field* (*of characteristic* 0) *has a unique algebraic closure* (§IV.5).
11. *Every countable formally real field is orderable* (§IV.4).
12. *Every countable formally real field has a* (*unique*) *real closure* (§IV.4).
13. *Brouwer's fixed point theorem*: *Every uniformly continuous function* $\phi\colon [0,1]^n \to [0,1]^n$ *has a fixed point* (§IV.7).
14. *The separable Hahn/Banach theorem*: *If* $f$ *is a bounded linear functional on a subspace of a separable Banach space, and if* $\|f\| \leq 1$, *then* $f$ *has an extension* $\widetilde{f}$ *to the whole space such that* $\|\widetilde{f}\| \leq 1$ (§IV.9).

Remark I.10.4 (mathematics within $\mathsf{WKL}_0$). Theorem I.10.3 illustrates how $\mathsf{WKL}_0$ is much stronger than $\mathsf{RCA}_0$ from the viewpoint of mathematical practice. In fact, $\mathsf{WKL}_0$ is strong enough to prove many well known nonconstructive theorems that are extremely important for mathematical practice but not true in the $\omega$-model REC, hence not provable in $\mathsf{RCA}_0$ (see §I.8).

Remark I.10.5 (first order part of $\mathsf{WKL}_0$). We have seen that $\mathsf{WKL}_0$ is much stronger than $\mathsf{RCA}_0$ with respect to both $\omega$-models (remark I.10.2) and mathematical practice (theorem I.10.3, remark I.10.4). Nevertheless, it can be shown that $\mathsf{WKL}_0$ is of the same strength as $\mathsf{RCA}_0$ in a proof-theoretic sense. Namely, the first order part of $\mathsf{WKL}_0$ is the same as that of $\mathsf{RCA}_0$, *viz*. $\Sigma^0_1$-PA. (See also remark I.7.6.) In fact, given any model $M$ of $\mathsf{RCA}_0$, there exists a model $M' \supseteq M$ of $\mathsf{WKL}_0$ having the same first order part as $M$. This model-theoretic conservation result will be proved in §IX.2.

Another key conservation result is that $\mathsf{WKL}_0$ is conservative over the formal system known as PRA or *primitive recursive arithmetic*, with respect to $\Pi^0_2$ sentences. In particular, given a $\Sigma^0_1$ formula $\varphi(m,n)$ and a proof of $\forall m\, \exists n\, \varphi(m,n)$ in $\mathsf{WKL}_0$, we can find a primitive recursive function $f\colon \omega \to \omega$ such that $\varphi(m, f(m))$ holds for all $m \in \omega$. This interesting and important result will be proved in §IX.3.

REMARK I.10.6 (Hilbert's program). The results of chapters IV and IX are of great importance with respect to the foundations of mathematics, specifically Hilbert's program. Hilbert's intention [114] was to justify all of mathematics (including infinitistic, set-theoretic mathematics) by reducing it to a restricted form of reasoning known as finitism. Gödel's [94, 115, 55, 222] limitative results show that there is no hope of realizing Hilbert's program completely. However, results along the lines of theorem I.10.3 and remark I.10.5 show that a large portion of infinitistic mathematical practice is in fact finitistically reducible, because it can be carried out in $\mathsf{WKL}_0$. Thus we have a significant partial realization of Hilbert's program of finitistic reductionism. See also remark IX.3.18.

**Notes for §I.10.** The formal system $\mathsf{WKL}_0$ was first introduced by Friedman [69]. In the model-theoretic literature, $\omega$-models of $\mathsf{WKL}_0$ are sometimes known as *Scott systems*, referring to Scott [217]. Chapter IV of this book is devoted to the development of mathematics within $\mathsf{WKL}_0$ and Reverse Mathematics for $\mathsf{WKL}_0$. Models of $\mathsf{WKL}_0$ are discussed in §§VIII.2, IX.2, and IX.3 of this book. The original paper on Hilbert's program is Hilbert [114]. The significance of $\mathsf{WKL}_0$ and Reverse Mathematics for partial realizations of Hilbert's program is expounded in Simpson [246].

## I.11. The System $\mathsf{ATR}_0$

In this section we introduce and discuss $\mathsf{ATR}_0$, a subsystem of $\mathsf{Z}_2$ consisting of $\mathsf{ACA}_0$ plus a set existence axiom known as *arithmetical transfinite recursion*. Informally, arithmetical transfinite recursion can be described as the assertion that the Turing jump operator can be iterated along any countable well ordering starting at any set. The precise statement is given in definition I.11.1 below.

From the standpoint of foundations of mathematics, the motivation for $\mathsf{ATR}_0$ is similar to the motivation for $\mathsf{WKL}_0$, as explained in §I.10. (See also the analogy in I.11.7 below.) Using the notation of §I.9, $\mathsf{ATR}_0 = S_4$ is intermediate between $\mathsf{ACA}_0 = S_3$ and $\Pi^1_1\text{-}\mathsf{CA}_0 = S_5$. It turns out that $\mathsf{ATR}_0$ is equivalent to several theorems of ordinary mathematics which are provable in $\Pi^1_1\text{-}\mathsf{CA}_0$ but not in $\mathsf{ACA}_0$.

As an example, consider the *perfect set theorem*: Every uncountable closed set (or analytic set) has a perfect subset. We shall see that $\mathsf{ATR}_0$ is equivalent over $\mathsf{RCA}_0$ to (either form of) the perfect set theorem. Thus $\mathsf{ATR}_0$ is the weakest natural subsystem of $\mathsf{Z}_2$ in which the perfect set theorem is provable. Actually, $\mathsf{ATR}_0$ provides the answer not only to this instance of the Main Question (§I.9) but also to many other instances of it; see theorem I.11.5 below. Moreover, $\mathsf{ATR}_0$ is sufficiently strong to accommodate a large portion of mathematical practice beyond $\mathsf{ACA}_0$,

including many basic theorems of infinitary combinatorics and classical descriptive set theory.

We now proceed to the definition of $\mathsf{ATR}_0$.

Definition I.11.1 (arithmetical transfinite recursion). Consider an arithmetical formula $\theta(n, X)$ with a free number variable $n$ and a free set variable $X$. Note that $\theta(n, X)$ may also contain parameters, i.e., additional free number and set variables. Fixing these parameters, we may view $\theta$ as an "arithmetical operator" $\Theta\colon P(\mathbb{N}) \to P(\mathbb{N})$, defined by

$$\Theta(X) = \{n \in \mathbb{N}\colon \theta(n, X)\}.$$

Now let $A, <_A$ be any countable well ordering (definition I.6.1), and consider the set $Y \subseteq \mathbb{N}$ obtained by transfinitely iterating the operator $\Theta$ along $A, <_A$. This set $Y$ is defined by the following conditions: $Y \subseteq \mathbb{N} \times A$ and, for each $a \in A$, $Y_a = \Theta(Y^a)$, where $Y_a = \{m\colon (m, a) \in Y\}$ and $Y^a = \{(n, b)\colon n \in Y_b \wedge b <_A a\}$. Thus, for each $a \in A$, $Y^a$ is the result of iterating $\Theta$ along the initial segment of $A, <_A$ up to but not including $a$, and $Y_a$ is the result of applying $\Theta$ one more time.

Finally, *arithmetical transfinite recursion* is the axiom scheme asserting that such a set $Y$ exists, for every arithmetical operator $\Theta$ and every countable well ordering $A, <_A$. We define $\mathsf{ATR}_0$ to consist of $\mathsf{ACA}_0$ plus the scheme of arithmetical transfinite recursion. It is easy to see that $\mathsf{ATR}_0$ is a subsystem of $\Pi^1_1$-$\mathsf{CA}_0$, and we shall see below that it is a proper subsystem.

Example I.11.2 (the $\omega$-model ARITH). Recall the $\omega$-model

$$\begin{aligned}\mathrm{ARITH} &= \mathrm{Def}((\omega, +, \cdot, 0, 1, <)) \\ &= \{X \subseteq \omega\colon \exists n \in \omega\, X \leq_{\mathrm{T}} \mathrm{TJ}(n, \emptyset)\}\end{aligned}$$

consisting of all arithmetically definable subsets of $\omega$ (remarks I.3.3 and I.3.4). We have seen that ARITH is the minimum $\omega$-model of $\mathsf{ACA}_0$. Trivially for each $n \in \omega$ we have $\mathrm{TJ}(n, \emptyset) \in \mathrm{ARITH}$; here $\mathrm{TJ}(n, \emptyset)$ is the result of iterating the Turing jump operator $n$ times, i.e., along a finite well ordering of order type $n$. On the other hand, ARITH does not contain $\mathrm{TJ}(\omega, \emptyset)$, the result of iterating the Turing jump operator $\omega$ times, i.e., along the well ordering $(\omega, <)$. Thus ARITH fails to satisfy this instance of arithmetical transfinite recursion. Hence ARITH is not an $\omega$-model of $\mathsf{ATR}_0$.

Example I.11.3 (the $\omega$-model HYP). Another important $\omega$-model is

$$\begin{aligned}\mathrm{HYP} &= \{X \subseteq \omega\colon X \leq_{\mathrm{H}} \emptyset\} \\ &= \{X \subseteq \omega\colon X \text{ is hyperarithmetical}\} \\ &= \{X \subseteq \omega\colon \exists \alpha < \omega_1^{\mathrm{CK}}\, X \leq_{\mathrm{T}} \mathrm{TJ}(\alpha, \emptyset)\}.\end{aligned}$$

Here $\alpha$ ranges over the recursive ordinals, i.e., the countable ordinals which are order types of recursive well orderings of $\omega$. We use $\omega_1^{CK}$ to denote Church/Kleene $\omega_1$, i.e., the least nonrecursive ordinal. Clearly HYP is much larger than ARITH, and HYP contains many sets which are defined by arithmetical transfinite recursion. However, as we shall see in §VIII.3, HYP does not contain enough sets to be an $\omega$-model of $\mathsf{ATR}_0$.

REMARK I.11.4 ($\omega$-models of $\mathsf{ATR}_0$). In §§VII.2 and VIII.6 we shall prove two facts: (1) every $\beta$-model is an $\omega$-model of $\mathsf{ATR}_0$; (2) the intersection of all $\beta$-models is HYP, the $\omega$-model consisting of the hyperarithmetical sets. From this it follows that HYP, although not itself an $\omega$-model of $\mathsf{ATR}_0$, is the intersection of all such $\omega$-models. Hence $\mathsf{ATR}_0$ does not have a minimum $\omega$-model or a minimum $\beta$-model. Combining these observations with what we already know about $\omega$-models of $\mathsf{ACA}_0$ and $\Pi^1_1$-$\mathsf{CA}_0$ (remarks I.3.4 and I.5.4), we see that

$$\mathsf{ACA}_0 \subsetneqq \mathsf{ATR}_0 \subsetneqq \Pi^1_1\text{-}\mathsf{CA}_0$$

and there are $\omega$-models for the independence.

We now list several results of Reverse Mathematics with respect to $\mathsf{ATR}_0$. These results will be proved in chapter V.

THEOREM I.11.5 (Reverse Mathematics for $\mathsf{ATR}_0$). *Within* $\mathsf{RCA}_0$ *one can prove that* $\mathsf{ATR}_0$ *is equivalent to each of the following ordinary mathematical statements*:

1. *Any two countable well orderings are comparable* (§V.6).
2. *Ulm's theorem*: *Any two countable reduced Abelian p-groups which have the same Ulm invariants are isomorphic* (§V.7).
3. *The perfect set theorem*: *Every uncountable closed, or analytic, set has a perfect subset* (§V.4, V.5).
4. *Lusin's separation theorem*: *Any two disjoint analytic sets can be separated by a Borel set* (§§V.3, V.5).
5. *The domain of any single-valued Borel set in the plane is a Borel set* (§V.3, V.5).
6. *Every open, or clopen, subset of* $\mathbb{N}^{\mathbb{N}}$ *is determined* (§V.8).
7. *Every open, or clopen, subset of* $[\mathbb{N}]^{\mathbb{N}}$ *has the Ramsey property* (§V.9).

REMARK I.11.6 (mathematics within $\mathsf{ATR}_0$). Theorem I.11.5 illustrates how $\mathsf{ATR}_0$ is much stronger than $\mathsf{ACA}_0$ from the viewpoint of mathematical practice. Namely, $\mathsf{ATR}_0$ proves many well known ordinary mathematical theorems which fail in the $\omega$-models ARITH and HYP and hence are not provable in $\mathsf{ACA}_0$ (see §I.4) or even in somewhat stronger systems such as $\Sigma^1_1$-$\mathsf{AC}_0$ (§VIII.4). A common feature of such theorems is that they require, implicitly or explicitly, a good theory of countable ordinal numbers.

Remark I.11.7 ($\Sigma^0_1$ and $\Sigma^1_1$ separation). From the viewpoint of mathematical practice, we have already noted an interesting analogy between $\mathsf{WKL}_0$ and $\mathsf{ATR}_0$, suggested by the following equation:

$$\frac{\mathsf{WKL}_0}{\mathsf{ACA}_0} \approx \frac{\mathsf{ATR}_0}{\Pi^1_1\text{-}\mathsf{CA}_0}.$$

We shall now extend this analogy by reformulating $\mathsf{WKL}_0$ and $\mathsf{ATR}_0$ in terms of separation principles.

Define $\Sigma^0_1$ *separation* to be the axiom scheme consisting of (the universal closures of) all formulas of the form

$$(\forall n\, \neg(\varphi_1(n) \wedge \varphi_2(n))) \rightarrow \\ \exists X\, (\forall n\, (\varphi_1(n) \rightarrow n \in X) \wedge \forall n\, (\varphi_2(n) \rightarrow n \notin X)),$$

where $\varphi_1(n)$ and $\varphi_2(n)$ are any $\Sigma^0_1$ formulas, $n$ is any number variable, and $X$ is a set variable which does not occur freely in $\varphi_1(n) \wedge \varphi_2(n)$. Define $\Sigma^1_1$ *separation* similarly, with $\Sigma^1_1$ formulas instead of $\Sigma^0_1$ formulas. It turns out that

$$\mathsf{WKL}_0 \equiv \Sigma^0_1 \text{ separation},$$

and

$$\mathsf{ATR}_0 \equiv \Sigma^1_1 \text{ separation},$$

over $\mathsf{RCA}_0$. These equivalences, which will be proved in §§IV.4 and V.5 respectively, serve to strengthen the above-mentioned analogy between $\mathsf{WKL}_0$ and $\mathsf{ATR}_0$. They will also be used as technical tools for proving several of the reversals given by theorems I.10.3 and I.11.5.

Remark I.11.8. Another analogy in the same vein as that of I.11.7 is

$$\frac{\mathsf{WKL}_0}{\mathsf{RCA}_0} \approx \frac{\mathsf{ATR}_0}{\Delta^1_1\text{-}\mathsf{CA}_0}.$$

The system $\Delta^1_1$-$\mathsf{CA}_0$ will be studied in §§VIII.3 and VIII.4, where we shall see that HYP is its minimum $\omega$-model. Recall also (remark I.7.5) that REC is the minimum $\omega$-model of

$$\mathsf{RCA}_0 \equiv \Delta^0_1\text{-}\mathsf{CA}_0.$$

Remark I.11.9 (first order part of $\mathsf{ATR}_0$). It is known that the first order part of $\mathsf{ATR}_0$ is the same as that of Feferman's system IR of predicative analysis; indeed, these two systems prove the same $\Pi^1_1$ sentences. Thus our development of mathematics within $\mathsf{ATR}_0$ (theorem I.11.5, remark I.11.6, chapter V) may be viewed as contributions to a program of "predicative reductionism," analogous to Hilbert's program of finitistic reductionism (remark I.10.6, section IX.3). See also the proof of theorem IX.5.7 below.

**Notes for §I.11.** The formal system $\mathsf{ATR}_0$ was first investigated by Friedman [68, 69] (see also Friedman [62, chapter II]) and Steel [256, chapter I]. A key reference for $\mathsf{ATR}_0$ is Friedman/McAloon/Simpson [76]. Chapter V of this book is devoted to the development of mathematics within $\mathsf{ATR}_0$ and Reverse Mathematics for $\mathsf{ATR}_0$. Models of $\mathsf{ATR}_0$ are discussed in §§VII.2, VII.3 and VIII.6. The basic reference for formal systems of predicative analysis is Feferman [56, 57]. The significance of $\mathsf{ATR}_0$ for predicative reductionism has been discussed by Simpson [238, 246].

## I.12. The Main Question, Revisited

The Main Question was introduced in §I.1. We now reexamine it in light of the results outlined in §§I.2 through I.11.

The Main Question asks which set existence axioms are needed to support ordinary mathematical reasoning. We take "needed" to mean that the set existence axioms are to be as weak as possible. When developing precise formal versions of the Main Question, it is natural also to consider formal languages which are as weak as possible. The language $\mathsf{L}_2$ comes to mind because it is just adequate to define the majority of ordinary mathematical concepts and to express the bulk of ordinary mathematical reasoning. This leads in §I.2 to the consideration of subsystems of $\mathsf{Z}_2$.

Two of the most obvious subsystems of $\mathsf{Z}_2$ are $\mathsf{ACA}_0$ and $\Pi^1_1$-$\mathsf{CA}_0$, and in §§I.3–I.6 we outline the development of ordinary mathematics in these systems. The upshot of this is that a great many ordinary mathematical theorems are provable in $\mathsf{ACA}_0$, and that of the exceptions, most are provable in $\Pi^1_1$-$\mathsf{CA}_0$. The exceptions tend to involve countable ordinal numbers, either explicitly or implicitly. Another important subsystem of $\mathsf{Z}_2$ is $\mathsf{RCA}_0$, which is seen in §§I.7 and I.8 to embody a kind of formalized computable or constructive mathematics. Thus we have an approximate answer to the Main Question.

We then turn to a sharpened form of the Main Question, where we insist that the ordinary mathematical theorems should be logically equivalent to the set existence axioms needed to prove them. Surprisingly, this demand can be met in some cases; several ordinary mathematical theorems turn out to be equivalent over $\mathsf{RCA}_0$ to either $\mathsf{ACA}_0$ or $\Pi^1_1$-$\mathsf{CA}_0$. This is our theme of Reverse Mathematics in §I.9. But the situation is not entirely satisfactory, because many ordinary mathematical theorems seem to fall into the gaps.

In order to improve the situation, we introduce two additional systems: $\mathsf{WKL}_0$ lying strictly between $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$, and analogously $\mathsf{ATR}_0$ lying strictly between $\mathsf{ACA}_0$ and $\Pi^1_1$-$\mathsf{CA}_0$. These systems are introduced in §§I.10 and I.11 respectively. With this expanded complement of subsystems of $\mathsf{Z}_2$, a certain stability is achieved; it now seems possible to "calibrate" a

great many ordinary mathematical theorems, by showing that they are either provable in $\mathsf{RCA}_0$ or equivalent over $\mathsf{RCA}_0$ to $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$, or $\Pi^1_1$-$\mathsf{CA}_0$.

Historically, the intermediate systems $\mathsf{WKL}_0$ and $\mathsf{ATR}_0$ were discovered in exactly in this way, as a response to the needs of Reverse Mathematics. See for example the discussion in Simpson [246, §§4,5].

From the above it is clear that the five basic systems $\mathsf{RCA}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$, $\Pi^1_1$-$\mathsf{CA}_0$ arise naturally from investigations of the Main Question. The proof that these systems are mathematically natural is provided by Reverse Mathematics.

As a perhaps not unexpected byproduct, we note that these same five systems turn out to correspond to various well known, philosophically motivated programs in foundations of mathematics, as indicated in table 1. The foundational programs that we have in mind are: Bishop's program of constructivism [20] (see however remarks I.8.9 and IV.2.8); Hilbert's program of finitistic reductionism [114, 246] (see remarks I.10.6 and IX.3.18); Weyl's program of predicativity [274] as developed by Feferman [56, 57, 59]; predicative reductionism as developed by Friedman and Simpson [69, 76, 238, 247]; impredicativity as developed in Buchholz/Feferman/Pohlers/Sieg [29]. Thus, by studying the formalization of mathematics and Reverse Mathematics for the five basic systems, we can develop insight into the mathematical consequences of these philosophical proposals. Thus we can expect this book and other Reverse Mathematics studies to have a substantial impact on the philosophy of mathematics.

Table 1. Foundational programs and the five basic systems.

| | | |
|---|---|---|
| $\mathsf{RCA}_0$ | constructivism | Bishop |
| $\mathsf{WKL}_0$ | finitistic reductionism | Hilbert |
| $\mathsf{ACA}_0$ | predicativism | Weyl, Feferman |
| $\mathsf{ATR}_0$ | predicative reductionism | Friedman, Simpson |
| $\Pi^1_1$-$\mathsf{CA}_0$ | impredicativity | Feferman *et al.* |

## I.13. Outline of Chapters II through X

This section of our introductory chapter I consists of an outline of the remaining chapters.

The bulk of the material is organized in two parts. Part A consists of chapters II through VI and focuses on the development of mathematics

within the five basic systems: $\mathsf{RCA}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$, $\Pi^1_1$-$\mathsf{CA}_0$. A principal theme of Part A is Reverse Mathematics (see also §I.9). Part B, consisting of chapters VII through IX, is concerned with metamathematical properties of various subsystems of $\mathsf{Z}_2$, including but not limited to the five basic systems. Chapters VII, VIII, and IX deal with $\beta$-models, $\omega$-models, and non-$\omega$-models, respectively. At the end of the book there is an appendix, chapter X, in which additional results are presented without proof but with references to the published literature. See also table 2.

TABLE 2. An overview of the entire book.

| | | |
|---|---|---|
| Introduction | Chapter I | introductory survey |
| Part A (mathematics within the 5 basic systems) | Chapter II | $\mathsf{RCA}_0$ |
| | Chapter III | $\mathsf{ACA}_0$ |
| | Chapter IV | $\mathsf{WKL}_0$ |
| | Chapter V | $\mathsf{ATR}_0$ |
| | Chapter VI | $\Pi^1_1$-$\mathsf{CA}_0$ |
| Part B (models of various systems) | Chapter VII | $\beta$-models |
| | Chapter VIII | $\omega$-models |
| | Chapter IX | non-$\omega$-models |
| Appendix | Chapter X | additional results |

**Part A: Mathematics Within Subsystems of $\mathsf{Z}_2$.** Part A consists of a key chapter II on the development of ordinary mathematics within $\mathsf{RCA}_0$, followed by chapters III, IV, V, and VI on ordinary mathematics within the other four basic systems: $\mathsf{ACA}_0$, $\mathsf{WKL}_0$, $\mathsf{ATR}_0$, and $\Pi^1_1$-$\mathsf{CA}_0$, respectively. These chapters present many results of Reverse Mathematics showing that particular set existence axioms are necessary and sufficient to prove particular ordinary mathematical theorems. Table 3 indicates in more detail exactly where some of these results may be found. Table 3 may serve as a guide or road map concerning the role of set existence axioms in ordinary mathematical reasoning.

**Chapter II: $\mathsf{RCA}_0$.** In §II.1 we define the formal system $\mathsf{RCA}_0$ consisting of $\Delta^0_1$ comprehension and $\Sigma^0_1$ induction. After that, the rest of chapter II is concerned with the development of ordinary mathematics within $\mathsf{RCA}_0$. Although chapter II does not itself contain any Reverse Mathematics, it is necessarily a prerequisite for all of the Reverse Mathematics results to be presented in later chapters. This is because $\mathsf{RCA}_0$ serves as our weak base theory (see §I.9 above).

Table 3. Ordinary mathematics within the five basic systems.

| | $\mathsf{RCA}_0$ | $\mathsf{WKL}_0$ | $\mathsf{ACA}_0$ | $\mathsf{ATR}_0$ | $\Pi^1_1$-$\mathsf{CA}_0$ |

| infinite games | | | V.8 | V.8 | VI.5 |

In §II.2 we employ a device reminiscent of *Gödel's beta function* to prove within $\mathsf{RCA}_0$ that finite sequences of natural numbers can be encoded as single numbers. This encoding is essential for §II.3, where we prove within $\mathsf{RCA}_0$ that the class of functions from $f : \mathbb{N}^k \to \mathbb{N}$, $k \in \mathbb{N}$, is closed under *primitive recursion*. Another key technical result of §II.3 is that $\mathsf{RCA}_0$ proves *bounded* $\Sigma^0_1$ *comprehension*, i.e., the existence of bounded subsets of $\mathbb{N}$ defined by $\Sigma^0_1$ formulas.

Armed with these preliminary results from §§II.2 and II.3, we begin the development of mathematics proper in §II.4 by discussing the *number systems* $\mathbb{N}$, $\mathbb{Z}$, $\mathbb{Q}$, and $\mathbb{R}$. Also in §II.4 we present an important completeness property of the real number system, known as *nested interval completeness*. An $\mathsf{RCA}_0$ version of the *Baire category theorem* for $k$-dimensional Euclidean spaces $\mathbb{R}^k$, $k \in \mathbb{N}$, is stated; the proof is postponed to §II.5.

Sections II.5, II.6, and II.7 discuss *complete separable metric spaces* in $\mathsf{RCA}_0$. Among the notions introduced (in a form appropriate for $\mathsf{RCA}_0$) are *open sets*, *closed sets*, and *continuous functions*. We prove the following

important technical result: An open set in a complete separable metric space $\widehat{A}$ is the same thing as a set in $\widehat{A}$ defined by a $\Sigma^0_1$ formula with an extensionality property (II.5.7). Nested interval completeness is used to prove the *intermediate value property* for continuous functions $\phi\colon \mathbb{R} \to \mathbb{R}$ in $\mathsf{RCA}_0$ (II.6.6). A number of basic topological results for complete separable metric spaces are shown to be provable in $\mathsf{RCA}_0$. Among these are *Urysohn's lemma* (II.7.3), the *Tietze extension theorem* (II.7.5), the *Baire category theorem* (II.5.8), and *paracompactness* (II.7.2).

Sections II.8 and II.9 deal with *mathematical logic* and *countable algebra*, respectively. We show in §II.8 that some surprisingly strong versions of basic results of mathematical logic can be proved in $\mathsf{RCA}_0$. Among these are *Lindenbaum's lemma*, the *Gödel completeness theorem*, and the *strong soundness theorem*, via *cut elimination*. To illustrate the power of these results, we show that $\mathsf{RCA}_0$ proves the consistency of *elementary function arithmetic*, EFA. In §II.9 we apply the results of §§II.3 and II.8 in a discussion of countable algebraically closed and real closed fields in $\mathsf{RCA}_0$. We use *quantifier elimination* to prove within $\mathsf{RCA}_0$ that every countable field has an *algebraic closure*, and that every countable ordered field has a *unique real closure*. (Uniqueness of algebraic closure is discussed later, in §IV.5.)

Section II.10 presents some basic concepts and results of the theory of *separable Banach spaces* and *bounded linear operators*, within $\mathsf{RCA}_0$. It is shown that the standard proof of the *Banach/Steinhaus uniform boundedness principle*, via the Baire category theorem, goes through in this setting.

**Chapter III: $\mathsf{ACA}_0$.** Chapter III is concerned with $\mathsf{ACA}_0$, the formal system consisting of $\mathsf{RCA}_0$ plus arithmetical comprehension. The focus of chapter III is Reverse Mathematics with respect to $\mathsf{ACA}_0$. (See also §§I.4, I.3, and I.9.)

In §III.1 we define $\mathsf{ACA}_0$ and show that it is equivalent over $\mathsf{RCA}_0$ to $\Sigma^0_1$ comprehension and to the principle that for any function $f : \mathbb{N} \to \mathbb{N}$, the range of $f$ exists. This equivalence is used to establish all of the Reverse Mathematics results which occupy the rest of the chapter. For example, it is shown in §III.2 that $\mathsf{ACA}_0$ is equivalent to the *Bolzano/Weierstraß theorem*, i.e., sequential compactness of the closed unit interval. Also in §III.2 we introduce the notion of *compact metric space*, and we show that $\mathsf{ACA}_0$ is equivalent to the principle that any sequence of points in a compact metric space has a convergent subsequence. We end §III.2 by showing that $\mathsf{ACA}_0$ is equivalent to the *Ascoli lemma* concerning bounded equicontinuous families of continuous functions.

Sections III.3, III.4, III.5 and III.6 are concerned with countable algebra in $\mathsf{ACA}_0$. It is perhaps interesting to note that chapter III has much more to say about algebra than about analysis.

We begin in §III.3 by reexamining the notion of an algebraic closure $h\colon K \to \widetilde{K}$ of a countable field $K$. We define a notion of *strong algebraic closure*, i.e., an algebraic closure with the additional property that the range of the embedding $h$ exists as a set. Although the existence of algebraic closures is provable in $\mathsf{RCA}_0$, we show in §III.3 that the existence of strong algebraic closures is equivalent to $\mathsf{ACA}_0$. Similarly, although it is provable in $\mathsf{RCA}_0$ that any countable ordered field has a real closure, we show in §III.3 that $\mathsf{ACA}_0$ is required to prove the existence of a *strong real closure*.

In §III.4 we show that $\mathsf{ACA}_0$ is equivalent to the theorem that every countable *vector space* over a countable field (or over the rational field $\mathbb{Q}$) has a basis. We then refine this result (following Metakides/Nerode [187]) by showing that $\mathsf{ACA}_0$ is also equivalent to the assertion that every countable, infinite dimensional vector space over $\mathbb{Q}$ has an infinite linearly independent set. We also obtain similar results for *transcendence bases* of countable fields.

In §III.5 we turn to countable commutative rings. We use localization to show that $\mathsf{ACA}_0$ is equivalent to the assertion that every countable commutative ring has a *maximal ideal*. In §III.6 we discuss *countable Abelian groups*. We show that $\mathsf{ACA}_0$ is equivalent to the assertion that, for every countable Abelian group $G$, the *torsion subgroup* of $G$ exists. We also show that, although the existence of *divisible closures* is provable in $\mathsf{RCA}_0$, the uniqueness requires $\mathsf{ACA}_0$

In §III.7 we consider *Ramsey's theorem*. We define $\mathrm{RT}(k)$ to be Ramsey's theorem for exponent $k$, i.e., the assertion that for every coloring of the $k$-element subsets of $\mathbb{N}$ with finitely many colors, there exists an infinite subset of $\mathbb{N}$ all of whose $k$-element subsets have the same color. We show that $\mathsf{ACA}_0$ is equivalent to $\mathrm{RT}(k)$ for each "standard integer" $k \in \omega$, $k \geq 3$. From the viewpoint of Reverse Mathematics, the case $k = 2$ turns out to be anomalous: $\mathrm{RT}(2)$ is provable in $\mathsf{ACA}_0$ but neither equivalent to $\mathsf{ACA}_0$ nor provable in $\mathsf{WKL}_0$. See also the notes at the end of §III.7. Another somewhat annoying anomaly is that the general assertion of Ramsey's theorem, $\forall k\ \mathrm{RT}(k)$, is slightly stronger than $\mathsf{ACA}_0$, due to the fact that $\mathsf{ACA}_0$ lacks full induction.

An interesting technical result of §III.7 is that $\mathsf{ACA}_0$ is equivalent to *König's lemma*: every infinite, finitely branching tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ has an infinite path. It turns out that $\mathsf{ACA}_0$ is also equivalent to a much weaker sounding statement, namely König's lemma restricted to *binary trees*. (A tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ is defined to be binary if each node of $T$ has at most two immediate successors.) The binary tree version of König's lemma is to be contrasted with its special case, *weak König's lemma*: every infinite tree $T \subseteq 2^{<\mathbb{N}}$ has an infinite path. It is important to understand that, in terms of set existence axioms and Reverse Mathematics, weak König's lemma is much weaker than König's lemma for binary trees. These observations

provide a transition to the next chapter, which is concerned only with weak König's lemma and not at all with König's lemma for binary trees.

**Chapter IV: $\mathsf{WKL}_0$.** Chapter IV focuses on Reverse Mathematics with respect to the formal system $\mathsf{WKL}_0$ consisting of $\mathsf{RCA}_0$ plus weak König's lemma. (See also the previous paragraph and §I.10.)

We begin in §IV.1 by showing that weak König's lemma is equivalent over $\mathsf{RCA}_0$ to the *Heine/Borel covering lemma*: every covering of the closed unit interval $[0, 1]$ by a sequence of open intervals has a finite subcovering. We then generalize this result by showing that $\mathsf{WKL}_0$ proves a Heine/Borel covering property for arbitrary *compact metric spaces*. In order to obtain this generalization, we first prove a technical result: $\mathsf{WKL}_0$ proves *bounded König's lemma*, i.e., König's lemma for subtrees of $\mathbb{N}^{<\mathbb{N}}$ which are bounded. (A tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ is said to be *bounded* if there exists a function $g : \mathbb{N} \to \mathbb{N}$ such that $\tau(m) < g(m)$ for all $\tau \in T$, $m < \mathrm{lh}(\tau)$.) We also develop some additional technical results which are needed in later sections.

Section IV.2 shows that various properties of continuous functions on compact metric spaces are provable in $\mathsf{WKL}_0$ and in fact equivalent to weak König's lemma over $\mathsf{RCA}_0$. Among the properties considered are *uniform continuity*, *Riemann integrability*, the *Weierstraß polynomial approximation theorem*, and the *maximum principle*. A key technical notion here is that of *modulus of uniform continuity* (definition IV.2.1).

In §IV.3 we return to mathematical logic. We show that several well known theorems of mathematical logic, such as the *completeness theorem* and the *compactness theorem* for both propositional logic and predicate calculus, are each equivalent to weak König's lemma over $\mathsf{RCA}_0$. Our results here in §IV.3 are to be contrasted with those of §II.8.

Sections IV.4, IV.5 and IV.6 deal with countable algebra in $\mathsf{WKL}_0$. We show in §IV.5 that weak König's lemma is equivalent to the assertion that every countable field has a *unique algebraic closure*. (We have already seen in §II.9 that the *existence* of algebraic closures is provable in $\mathsf{RCA}_0$.) In §IV.4 we discuss *formally real fields*, i.e., fields in which $-1$ cannot be written as a sum of squares. We show that weak König's lemma is equivalent over $\mathsf{RCA}_0$ to the assertion that every countable formally real field is *orderable*, and to the assertion that every countable formally real field has a *real closure*. In order to prove these results of Reverse Mathematics, we first prove a technical result characterizing $\mathsf{WKL}_0$ in terms of $\Sigma^0_1$ *separation*; see also §I.11.

In §IV.6 we show that $\mathsf{WKL}_0$ proves the existence of *prime ideals* in countable commutative rings. The argument for this result is somewhat interesting in that it involves not only two applications of weak König's lemma but also bounded $\Sigma^0_1$ comprehension. In addition, we obtain reversals showing that weak König's lemma is equivalent over $\mathsf{RCA}_0$ to the existence of prime ideals, or even of radical ideals, in countable commutative rings. These results stand in contrast to §III.5, where we saw

that $\mathsf{ACA}_0$ is needed to prove the existence of *maximal ideals* in countable commutative rings. Thus it emerges that the usual textbook proof of the existence of prime ideals, via maximal ideals, is far from optimal with respect to its use of set existence axioms.

Sections IV.7, IV.8 and IV.9 are concerned with certain advanced topics in analysis. We begin in §IV.7 by showing that the well known *fixed point theorems* of Brouwer and Schauder are provable in $\mathsf{WKL}_0$. In §IV.8 we use a fixed point technique to prove *Peano's existence theorem for solutions of ordinary differential equations*, in $\mathsf{WKL}_0$. We also obtain reversals showing weak König's lemma is needed to prove the Brouwer and Schauder fixed point theorems and Peano's existence theorem. On the other hand, we note that the more familiar *Picard existence and uniqueness theorem*, assuming a Lipschitz condition, is already provable in $\mathsf{RCA}_0$ alone.

Section IV.9 is concerned with Banach space theory in $\mathsf{WKL}_0$. We build on the concepts and results of §§II.10 and IV.7. We begin by showing that yet another fixed point theorem, the *Markov/Kakutani theorem* for commutative families of affine maps, is provable in $\mathsf{WKL}_0$. We then use this result to show that $\mathsf{WKL}_0$ proves a version of the *Hahn/Banach extension theorem* for bounded linear functionals on separable Banach spaces. A reversal is also obtained.

**Chapter V: $\mathsf{ATR}_0$.** Chapter V deals with mathematics in $\mathsf{ATR}_0$, the formal system consisting of $\mathsf{ACA}_0$ plus arithmetical transfinite recursion. (See also §I.11.) Many of the ordinary mathematical theorems considered in chapters V and VI are in the areas of countable combinatorics and classical descriptive set theory. The first few sections of chapter V focus on proving ordinary mathematical theorems in $\mathsf{ATR}_0$. Reverse Mathematics with respect to $\mathsf{ATR}_0$ is postponed to §V.5.

Chapter V begins with a preliminary §V.1 whose purpose is to elucidate the relationships among $\Sigma^1_1$ formulas, analytic sets, countable well orderings, and trees. An important tool is the *Kleene/Brouwer ordering* $\mathrm{KB}(T)$ of an arbitrary tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$. Key properties of the Kleene/Brouwer construction are: (1) $\mathrm{KB}(T)$ is always a linear ordering; (2) $\mathrm{KB}(T)$ is a well ordering if and only if $T$ is well founded. The Kleene normal form theorem is proved in $\mathsf{ACA}_0$ and is then used to show that any $\Pi^1_1$ assertion $\psi$ can be expressed in $\mathsf{ACA}_0$ by saying that an appropriately chosen tree $T_\psi$ is well founded, or equivalently, $\mathrm{KB}(T_\psi)$ is a well ordering.

In §V.2 we define the formal system $\mathsf{ATR}_0$ and observe that it is strong enough to accommodate a good theory of *countable ordinal numbers*, encoded by countable well orderings. In §V.3 we show that $\mathsf{ATR}_0$ is also strong enough to accommodate a good theory of *Borel and analytic sets* in the Cantor space $2^{\mathbb{N}}$. In this setting, the well known theorems of Souslin ("$B$ is Borel if and only if $B$ and its complement are analytic") and Lusin ("any two disjoint analytic sets can be separated by a Borel set") are proved, along with a lesser known closure property of Borel sets ("the

domain of a single-valued Borel relation is Borel"). In §V.4 we advance our examination of classical descriptive set theory by showing that the *perfect set theorem* ("every uncountable analytic set has a nonempty perfect subset") is provable in $\mathsf{ATR}_0$. This last result uses an interesting technique known as the *method of pseudohierarchies*, or "nonstandard H-sets", i.e., arithmetical transfinite recursion along countable linear orderings which are not well orderings.

In §V.5, most of the descriptive set-theoretic theorems mentioned in §§V.3 and V.4 are reversed, i.e., shown to be equivalent over $\mathsf{RCA}_0$ to $\mathsf{ATR}_0$. The reversals are based on our characterization of $\mathsf{ATR}_0$ in terms of $\Sigma^1_1$ *separation*. See also §I.11. We also present the following alternative characterization: $\mathsf{ATR}_0$ is equivalent to the assertion that, for any sequence of trees $\langle T_i : i \in \mathbb{N}\rangle$, if each $T_i$ has at most one path, then the set $\{i : T_i$ has a path$\}$ exists. This equivalence is based on a sharpening of the Kleene normal form theorem.

We have already observed that the development of mathematics within $\mathsf{ATR}_0$ seems to go hand in hand with a good theory of countable ordinal numbers. In §V.6 we sharpen this observation by showing that $\mathsf{ATR}_0$ is actually equivalent over $\mathsf{RCA}_0$ to a certain statement which is obviously indispensable for any such theory. The statement in question is, "any two countable well orderings are comparable", abbreviated CWO. The proof that CWO implies $\mathsf{ATR}_0$ is rather technical and uses what are called *double descent trees*.

In §V.7 we return to the study of countable Abelian groups (see also §§III.6 and VI.4). We show that $\mathsf{ATR}_0$ is needed to prove *Ulm's theorem* for reduced Abelian $p$-groups, as well as some consequences of Ulm's theorem. The reversals use the fact that $\mathsf{ATR}_0$ is equivalent to CWO. Ulm's theorem is of interest with respect to our Main Question, because it seems to be one of the few places in analysis or algebra where transfinite recursion plays an apparently indispensable role.

In §§V.8 and V.9 we consider two other topics in ordinary mathematics where strong set existence axioms arise naturally. These are (1) infinite game theory, and (2) the Ramsey property.

The games considered in §V.8 are Gale/Stewart games, i.e., infinite games with perfect information. A payoff set $S \subseteq \mathbb{N}^{\mathbb{N}}$ is specified. Two players take turns choosing nonnegative integers $m_1, n_1, m_2, n_2, \ldots$, with full disclosure. The first player is declared the winner if the infinite sequence $\langle m_1, n_1, m_2, n_2, \ldots\rangle$ belongs to $S$. Otherwise the second player is declared the winner. Such a game is said to be *determined* if one player or the other has a winning strategy. Letting $\mathcal{S}$ be any class of payoff sets, $\mathcal{S}$-*determinacy* is the assertion that all games of this class are determined. It is well known that strong set existence axioms are correlated to determinacy for large classes of games. A striking result of this kind is due to Friedman

[66, 71], who showed that Borel determinacy requires $\aleph_1$ applications of the power set axiom.

We show in §V.8 that $\mathsf{ATR}_0$ proves *open determinacy*, i.e., determinacy for all games in which the payoff set $S \subseteq \mathbb{N}^{\mathbb{N}}$ is open. This result uses pseudohierarchies, just as for the perfect set theorem. We also obtain a reversal, showing that open determinacy or even *clopen determinacy* is equivalent to $\mathsf{ATR}_0$ over $\mathsf{RCA}_0$. Our argument for the reversal proceeds via CWO. Along the way we obtain the following preliminary result: *determinacy for games of length* 3 is equivalent to $\mathsf{ACA}_0$ over $\mathsf{RCA}_0$.

As a consequence of open determinacy in $\mathsf{ATR}_0$, we obtain the following interesting theorem: $\mathsf{ATR}_0$ proves the $\Sigma^1_1$ *axiom of choice*. (More information on $\Sigma^1_1$ choice is in §VIII.4.)

In §V.9 we deal with a well known topological generalization of Ramsey's theorem. Let $[\mathbb{N}]^{\mathbb{N}}$ be the *Ramsey space*, i.e., the space of all infinite subsets of $\mathbb{N}$. Note that $[\mathbb{N}]^{\mathbb{N}}$ is canonically homeomorphic to the Baire space $\mathbb{N}^{\mathbb{N}}$ via $\Phi\colon [\mathbb{N}]^{\mathbb{N}} \cong \mathbb{N}^{\mathbb{N}}$ defined by

$$\Phi^{-1}(f) = \{f(0) + 1 + \cdots + 1 + f(n)\colon n \in \mathbb{N}\}.$$

A set $S \subseteq [\mathbb{N}]^{\mathbb{N}}$ is said to have the *Ramsey property* if there exists $X \in [\mathbb{N}]^{\mathbb{N}}$ such that either $[X]^{\mathbb{N}} \subseteq S$ or $[X]^{\mathbb{N}} \cap S = \emptyset$. (Here $[X]^{\mathbb{N}}$ denotes the set of infinite subsets of $X$.) The main result of §V.9 is that $\mathsf{ATR}_0$ is equivalent over $\mathsf{RCA}_0$ to the *open Ramsey theorem*, i.e., the assertion that every open subset of $[\mathbb{N}]^{\mathbb{N}}$ has the Ramsey property. The *clopen Ramsey theorem* is also seen to be equivalent over $\mathsf{RCA}_0$ to $\mathsf{ATR}_0$.

**Chapter VI: $\Pi^1_1$-$\mathsf{CA}_0$.** Chapter VI is concerned with mathematics and Reverse Mathematics with respect to the formal system $\Pi^1_1$-$\mathsf{CA}_0$, consisting of $\mathsf{ACA}_0$ plus $\Pi^1_1$ comprehension. We show that $\Pi^1_1$-$\mathsf{CA}_0$ is just strong enough to prove several theorems of ordinary mathematics. It is interesting to note that several of these ordinary mathematical theorems, which are equivalent to $\Pi^1_1$ comprehension, have "$\mathsf{ATR}_0$ counterparts" which are equivalent to arithmetical transfinite recursion. Thus chapter VI on $\Pi^1_1$-$\mathsf{CA}_0$ goes hand in hand with chapter V on $\mathsf{ATR}_0$.

In §§VI.1 through VI.3 we consider several well known theorems of *classical descriptive set theory* in $\Pi^1_1$-$\mathsf{CA}_0$. We begin in §VI.1 by showing that the *Cantor/Bendixson theorem* ("every closed set consists of a perfect set plus a countable set") is equivalent to $\Pi^1_1$ comprehension. This result for the Baire space $\mathbb{N}^{\mathbb{N}}$ and the Cantor space $2^{\mathbb{N}}$ is closely related to an analysis of trees in $\mathbb{N}^{<\mathbb{N}}$ and $2^{<\mathbb{N}}$, respectively. The $\mathsf{ATR}_0$ counterpart of the Cantor/Bendixson theorem is, of course, the perfect set theorem (§V.4).

In §VI.2 we show that *Kondo's theorem* (coanalytic uniformization) is provable in $\Pi^1_1$-$\mathsf{CA}_0$ and in fact equivalent to $\Pi^1_1$ comprehension over $\mathsf{ATR}_0$. The reversal uses an $\mathsf{ATR}_0$ formalization of *Suzuki's theorem* on $\Pi^1_1$ singletons.

In §VI.3 we consider *Silver's theorem*: For any coanalytic equivalence relation with uncountably many equivalence classes, there exists a nonempty perfect set of inequivalent elements. We show that a certain carefully stated reformulation of Silver's theorem is provable in $\mathsf{ATR}_0$. (See lemma VI.3.1. The proof of this lemma is somewhat technical and uses *formalized hyperarithmetical theory* (§VIII.3) as well as *Gandy forcing* over countable coded $\omega$-models.) We then use this $\mathsf{ATR}_0$ result to show that Silver's theorem itself is provable in $\Pi^1_1$-$\mathsf{CA}_0$. We also present a reversal showing that Silver's theorem specialized to $\Delta^0_2$ equivalence relations is equivalent to $\Pi^1_1$ comprehension over $\mathsf{RCA}_0$ (theorem VI.3.6).

In §VI.4 we resume our study of countable algebra. We show that $\Pi^1_1$ comprehension is equivalent over $\mathsf{RCA}_0$ to the assertion that every countable Abelian group can be written as the direct sum of a divisible group and a reduced group. The $\mathsf{ATR}_0$ counterpart of this assertion is Ulm's theorem (§V.7). Combining these results, we see that $\Pi^1_1$-$\mathsf{CA}_0$ is just strong enough to develop the classical *structure theory of countable Abelian groups* as presented in, for instance, Kaplansky [136].

In §§VI.5 and VI.6 we resume our study of determinacy and the Ramsey property. We show that $\Pi^1_1$ comprehension is just strong enough to prove $\Sigma^0_1 \wedge \Pi^0_1$ *determinacy* and the $\Delta^0_2$ *Ramsey theorem*. The $\mathsf{ATR}_0$ counterparts of these results are, of course, $\Sigma^0_1$ determinacy (i.e., open determinacy) and the $\Sigma^0_1$ Ramsey theorem (i.e., the open Ramsey theorem). Our proof technique in §VI.6 uses countable coded $\beta$-models (§VII.2).

Section VI.7 serves as an appendix to §§VI.5 and VI.6. In it we remark that stronger forms of Ramsey's theorem and determinacy require *stronger set existence axioms*. For instance, the $\Delta^1_1$ *Ramsey theorem* (i.e., the Galvin/Prikry theorem) and $\Delta^0_2$ *determinacy* each require $\Pi^1_1$ *transfinite recursion* (theorem VI.7.3). Moreover, there are yet stronger forms of Ramsey's theorem and determinacy which go beyond $\mathsf{Z}_2$ (remarks VI.7.6 and VI.7.7).

Note: The results in §VI.7 are stated without proof but with appropriate references to the published literature.

This completes our summary of Part A.

**Part B: Models of Subsystems of $\mathsf{Z}_2$.** Part B is a fairly thorough study of metamathematical properties of subsystems of $\mathsf{Z}_2$. We consider not only the five basic systems $\mathsf{RCA}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$, and $\Pi^1_1$-$\mathsf{CA}_0$ but also many other systems, including $\Delta^1_k$-$\mathsf{CA}_0$ ($\Delta^1_k$ comprehension), $\Pi^1_k$-$\mathsf{CA}_0$ ($\Pi^1_k$ comprehension), $\Sigma^1_k$-$\mathsf{AC}_0$ ($\Sigma^1_k$ choice), $\Sigma^1_k$-$\mathsf{DC}_0$ ($\Sigma^1_k$ dependent choice), $\Pi^1_k$-$\mathsf{TR}_0$ ($\Pi^1_k$ transfinite recursion), and $\Pi^1_k$-$\mathsf{TI}_0$ ($\Pi^1_k$ transfinite induction), for arbitrary $k$ in the range $1 \leq k \leq \infty$. Table 4 lists these systems in order of increasing *logical strength*, also known as *consistency strength*.

We have found it convenient to divide the metamathematical material of Part B into three chapters dealing with *$\beta$-models*, *$\omega$-models*, and

*non-$\omega$-models* respectively. This threefold partition is perhaps somewhat misleading, and there are many cross-connections among the three chapters. This is mostly because the chapters which are ostensibly about $\beta$- and $\omega$-models actually present their results in greater generality, so as to apply also to $\beta$- and $\omega$-*submodels* of a given model, which need not itself be a $\beta$- or $\omega$-model. Table 4 indicates where the main results concerning $\beta$-, $\omega$- and non-$\omega$-models of the various systems may be found.

**Chapter VII: $\beta$-models.** Recall from definition I.5.3 that a *$\beta$-model* is an $\omega$-model $M$ such that for any arithmetical formula $\theta(X)$ with parameters from $M$, if $\exists X\,\theta(X)$ then $(\exists X \in M)\,\theta(X)$. Such models are of importance because the concept of well ordering is absolute to them.

Throughout chapter VII, we find it convenient to consider a more general notion: $M$ is a *$\beta$-submodel of $M'$* if $M$ is a submodel of $M'$ and, for all arithmetical formulas $\theta(X)$ with parameters from $M$, $M \models \exists X\,\theta(X)$ if and only if $M' \models \exists X\,\theta(X)$. Thus a $\beta$-model is the same thing as a $\beta$-submodel of the intended model $P(\omega)$.

Section VII.1 is introductory in nature. In it we characterize $\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$ in terms of familiar recursion-theoretic notions. Namely, $M$ is a $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$ if and only if $M$ is closed under *relative recursiveness* and the *hyperjump*. We also obtain the obvious generalization to $\beta$-submodels. This is based on a formalized $\mathsf{ACA}_0$ version of the *Kleene basis theorem*, according to which the sets recursive in $\mathrm{HJ}(X)$ form a basis for predicates which are arithmetical in $X$, provided $\mathrm{HJ}(X)$ exists.

In §VII.2 we consider *countable coded $\beta$-models*, i.e., $\beta$-models of the form $M = \{(W)_n : n \in \mathbb{N}\}$ where $W \subseteq \mathbb{N}$ and $(W)_n = \{m : (m,n) \in W\}$. Within $\mathsf{ACA}_0$ we define the notion of *satisfaction* for such models, and we prove within $\mathsf{ACA}_0$ that every such model satisfies $\mathsf{ATR}_0$ and all instances of the *transfinite induction scheme*, $\Pi^1_\infty$-$\mathsf{TI}_0$, given by

$$\forall X(\mathrm{WO}(X) \to \mathrm{TI}(X,\varphi))$$

where $\varphi$ is an arbitrary $\mathrm{L}_2$-formula. Here $\mathrm{WO}(X)$ says that $X$ is a countable well ordering, and $\mathrm{TI}(X,\varphi)$ expresses transfinite induction along $X$ with respect to $\varphi$. We also prove within $\mathsf{ACA}_0$ that if $\mathrm{HJ}(X)$ exists then there is a countable coded $\beta$-model $M \leq_{\mathrm{T}} \mathrm{HJ}(X)$ such that $X \in M$. These considerations have a number of interesting consequences: (1) $\Pi^1_\infty$-$\mathsf{TI}_0$ includes $\mathsf{ATR}_0$; (2) $\Pi^1_\infty$-$\mathsf{TI}_0$ is not finitely axiomatizable; (3) there exists a $\beta$-model of $\Pi^1_\infty$-$\mathsf{TI}_0$ which is not a model of $\Pi^1_1$-$\mathsf{CA}_0$; (4) $\Pi^1_1$-$\mathsf{CA}_0$ proves the consistency of $\Pi^1_\infty$-$\mathsf{TI}_0$. We also obtain some technical results characterizing $\Pi^1_2$ sentences that are provable in $\Pi^1_\infty$-$\mathsf{TI}_0$ and in $\Pi^1_2$-$\mathsf{TI}_0$.

In §VII.3 we introduce set-theoretic methods. We employ the language $\mathrm{L}_{\mathrm{set}} = \{\in, =\}$ of Zermelo/Fraenkel set theory. Of key importance is an $\mathrm{L}_{\mathrm{set}}$-theory $\mathsf{ATR}^{\mathrm{set}}_0$, among whose axioms are the *Axiom of Countability*, asserting that all sets are hereditarily countable, and *Axiom Beta*, asserting that for any regular (i.e., well founded) binary relation $r$ there exists a

Notes:

1. Each of $\Pi^0_1$-$AC_0$ and $\Pi^0_1$-$DC_0$ and strong $\Pi^0_1$-$DC_0$ is equivalent to $WKL_0$. See lemma VIII.2.5.

Notes (cont.):

2. The $\omega$-model incompleteness theorem VIII.5.6 applies to any system $S \supseteq \mathsf{ACA}_0$. The $\omega$-model hard core theorem VIII.6.6 applies to any system $S \supseteq$ weak $\Sigma^1_1$-$\mathsf{AC}_0$. Quinsey's theorem VIII.6.12 applies to any system $S \supseteq \mathsf{ATR}_0$.
3. $\Pi^1_1$-$\mathsf{TI}_0$ is equivalent to $\Sigma^1_1$-$\mathsf{DC}_0$. See theorem VIII.5.12.
4. $\Sigma^1_2$-$\mathsf{AC}_0$ is equivalent to $\Delta^1_2$-$\mathsf{CA}_0$. $\Sigma^1_2$-$\mathsf{DC}_0$ is equivalent to $\Delta^1_2$-$\mathsf{CA}_0$ plus $\Sigma^1_2$ induction. Strong $\Sigma^1_1$-$\mathsf{DC}_0$ and strong $\Sigma^1_2$-$\mathsf{DC}_0$ are equivalent to $\Pi^1_1$-$\mathsf{CA}_0$ and $\Pi^1_2$-$\mathsf{CA}_0$, respectively. See remarks VII.6.3–VII.6.5 and theorem VII.6.9.

*collapsing function*, i.e., a function $f$ such that $f(u) = \{f(v) : \langle v, u\rangle \in r\}$ for all $u \in \mathrm{field}(r)$. By using well founded trees to encode hereditarily countable sets, we define a close relationship of mutual interpretability between $\mathsf{ATR}_0$ and $\mathsf{ATR}^{\mathrm{set}}_0$. Under this interpretation, $\Sigma^1_{k+1}$ formulas of $\mathrm{L}_2$ correspond to $\Sigma^{\mathrm{set}}_k$ formulas of $\mathrm{L}_{\mathrm{set}}$ (theorem VII.3.24). Thus any formal system $T_0 \supseteq \mathsf{ATR}_0$ in $\mathrm{L}_2$ is seen to have a *set-theoretic counterpart* $T^{\mathrm{set}}_0$ in $\mathrm{L}_{\mathrm{set}}$ (definition VII.3.33). We point out that several familiar subsystems of $\mathsf{Z}_2$ have elegant characterizations in terms of their set-theoretic counterparts. For instance, the principal axiom of $\Pi^0_\infty$-$\mathsf{TI}^{\mathrm{set}}_0$ is the $\in$-induction scheme, and the principal axiom of $\Sigma^1_2$-$\mathsf{AC}^{\mathrm{set}}_0$ is $\Sigma^{\mathrm{set}}_1$ collection.

In §VII.4 we explore Gödel's theory of *constructible sets* in a form appropriate for the study of subsystems of $\mathsf{Z}_2$. We begin by defining within $\mathsf{ATR}^{\mathrm{set}}_0$ the inner model $\mathrm{L}^u$ of sets constructible from $u$, where $u$ is any given nonempty transitive set. After that, we turn to *absoluteness results*. We prove within $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$ that the formula "$r$ is a regular relation" is absolute to $\mathrm{L}^u$. This fact is used to prove $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$ versions of the well known absoluteness theorems of Shoenfield and Lévy. We consider the inner models $\mathrm{L}(X)$ and $\mathrm{HCL}(X)$ of sets that are constructible from $X$ and *hereditarily constructibly countable* from $X$, respectively, where $X \subseteq \omega$. We prove within $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$ that $\mathrm{HCL}(X)$ satisfies $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$ plus $\mathrm{V} = \mathrm{HCL}(X)$, and that $\Sigma^1_2$ and $\Sigma^{\mathrm{set}}_1$ formulas are absolute to $\mathrm{HCL}(X)$. We prove within $\mathsf{ATR}^{\mathrm{set}}_0$ that if $\mathrm{HCL}(X) \neq \mathrm{L}(X)$ then $\mathrm{HCL}(X)$ satisfies $\Pi^1_\infty$-$\mathsf{CA}^{\mathrm{set}}_0$.

In §§VII.5, VII.6 and VII.7 we apply our results on constructible sets to the study of $\beta$-models of subsystems of second order arithmetic which are stronger than $\Pi^1_1$-$\mathsf{CA}_0$.

Section VII.5 is concerned with *strong comprehension schemes*. The main result is that if $T_0$ is any one of the systems $\Pi^1_1$-$\mathsf{CA}_0$, $\Delta^1_2$-$\mathsf{CA}_0$, $\Pi^1_2$-$\mathsf{CA}_0$, $\Delta^1_3$-$\mathsf{CA}_0$, ..., then $T_0$ implies its own relativization to the inner models $\mathrm{L}(X) \cap P(\mathbb{N})$, $X \subseteq \mathbb{N}$. This has several interesting consequences: (1) $T_0 + \exists X \forall Y\, (Y \in \mathrm{L}(X))$ is conservative over $T_0$ for $\Pi^1_4$ sentences; (2) $T_0$ has a *minimum $\beta$-model*, and this minimum $\beta$-model is of the form $\mathrm{L}_\alpha \cap P(\omega)$ where $\alpha$ is an appropriately chosen countable ordinal. (These minimum $\beta$-models and their corresponding ordinals turn out to be distinct from one another; see §VII.7.) We also present generalizations involving minimum $\beta$-submodels of a given model.

Section VII.6 is concerned with several *strong choice schemes*, i.e., instances of the axiom of choice expressible in the language of second order arithmetic. Among the schemes considered are $\Sigma^1_k$ *choice*

$$\forall n\, \exists Y \eta(n, Y) \to \exists Z\, \forall n\, \eta(n, (Z)_n),$$

$\Sigma^1_k$ *dependent choice*

$$\forall n\, \forall X\, \exists Y \eta(n, Y) \to \exists Z\, \forall n\, \eta(n, (Z)^n, (Z)_n),$$

and *strong* $\Sigma^1_k$ *dependent choice*

$$\exists Z\, \forall n\, \forall Y (\eta(n, (Z)^n, Y) \to \eta(n, (Z)^n, (Z)_n)).$$

The corresponding formal systems are known as $\Sigma^1_k$-$\mathsf{AC}_0$, $\Sigma^1_k$-$\mathsf{DC}_0$, and strong $\Sigma^1_k$-$\mathsf{DC}_0$, respectively. The case $k = 2$ is somewhat special. We show that $\Delta^1_2$ comprehension implies $\Sigma^1_2$ choice, and even $\Sigma^1_2$ dependent choice provided $\Sigma^1_2$ induction is assumed. We also show that strong $\Sigma^1_2$ dependent choice is equivalent to $\Pi^1_2$ comprehension. These equivalences for $k = 2$ are based on the fact that $\Sigma^1_2$ *uniformization* is provable in $\Pi^1_1$-$\mathsf{CA}_0$. Two proofs of this fact are given, one via Kondo's theorem and the other via Shoenfield absoluteness.

For $k \geq 3$ we obtain similar equivalences under the additional assumption $\exists X\, \forall Y\, (Y \in \mathrm{L}(X))$, via $\Sigma^1_k$ *uniformization*. We then apply our conservation theorems of the previous section to see that, for each $k \geq 3$, $\Sigma^1_k$ choice and strong $\Sigma^1_k$ dependent choice are conservative for $\Pi^1_4$ sentences over $\Delta^1_k$ comprehension and $\Pi^1_k$ comprehension, respectively. Other results of a similar character are obtained. The case $k = 1$ is of a completely different character, and its treatment is postponed to §VIII.4.

Section VII.7 begins by generalizing the concept of $\beta$-model to $\beta_k$-*model*, i.e., an $\omega$-model $M$ such that all $\Sigma^1_k$ formulas with parameters from $M$ are absolute to $M$. (Thus a $\beta_1$-model is the same thing as a $\beta$-model.) It is shown that, for each $k \geq 1$,

$$\forall X\, \exists M\, (X \in M \wedge M \text{ is a countable coded } \beta_k\text{-model})$$

is equivalent to strong $\Sigma^1_k$ dependent choice. This implies a kind of $\beta_k$-*model reflection principle* (theorem VII.7.6). Combining this with the results of §§VII.5 and VII.6, we obtain several noteworthy corollaries, e.g., the fact that $\Delta^1_{k+1}$-$\mathsf{CA}_0$ proves the existence of a countable coded $\beta$-model of $\Pi^1_k$-$\mathsf{CA}_0$ which in turn proves the existence of a countable coded $\beta$-model of $\Delta^1_k$-$\mathsf{CA}_0$. From this it follows that the minimum $\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$, $\Delta^1_2$-$\mathsf{CA}_0$, $\Pi^1_2$-$\mathsf{CA}_0$, $\Delta^1_3$-$\mathsf{CA}_0$, ... are all distinct.

**Chapter VIII: $\omega$-models.** The purpose of chapter VIII is to study $\omega$-models of various subsystems of $\mathsf{Z}_2$. We focus primarily on the five basic systems: $\mathsf{RCA}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$, $\Pi^1_1$-$\mathsf{CA}_0$. We note that each of these systems is finitely axiomatizable. We also obtain some general results about fairly arbitrarily $\mathrm{L}_2$-theories, which may be stronger than $\Pi^1_1$-$\mathsf{CA}_0$

and need not be finitely axiomatizable. Many of our results on $\omega$-models are formulated more generally, so as to apply also to $\omega$-submodels of a given non-$\omega$-model.

Section VIII.1 is introductory in nature. We characterize models of $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$ in terms of Turing reducibility and the Turing jump operator. We show that the *minimum $\omega$-models of* $\mathsf{RCA}_0$ *and* $\mathsf{ACA}_0$ are $\mathrm{REC} = \{X\colon X \text{ is recursive}\}$ and $\mathrm{ARITH} = \{X\colon X \text{ is arithmetical}\}$ respectively. We apply the strong soundness theorem and countable coded $\omega$-models to show that $\mathsf{ATR}_0$ proves the *consistency of* $\mathsf{ACA}_0$, which in turn proves the *consistency of* $\mathsf{RCA}_0$.

In §VIII.2 we consider models of $\mathsf{WKL}_0$. We begin by showing that $\mathsf{WKL}_0$ proves *strong* $\Pi^0_1$ *dependent choice*, which in turn implies the existence of a countable coded *strict $\beta$-model*. Such a model necessarily satisfies $\mathsf{WKL}_0$, so we are surprisingly close to asserting that $\mathsf{WKL}_0$ proves its own consistency (see however remark VIII.2.14). In particular, $\mathsf{ACA}_0$ actually does prove the *consistency of* $\mathsf{WKL}_0$, via countable coded $\omega$-models (corollary VIII.2.12). Moreover, $\mathsf{WKL}_0$ *has no minimal $\omega$-model* (corollary VIII.2.8).

The rest of §VIII.2 is concerned with the *basis problem*: Given an infinite recursive tree $T \subseteq 2^{<\omega}$, to find a path through $T$ which is in some sense "close to being recursive." We obtain three results, the *low basis theorem*, the *almost recursive basis theorem*, and the *GKT basis theorem*, which provide various solutions of the basis problem. They also imply the existence of *countable $\omega$-models of* $\mathsf{WKL}_0$ with various properties (theorems VIII.2.17, VIII.2.21, VIII.2.24). In particular, REC *is the intersection of all $\omega$-models of* $\mathsf{WKL}_0$ (corollary VIII.2.27).

In §VIII.3 we develop the technical machinery of *formalized hyperarithmetical theory*. We define the H-*sets* $\mathrm{H}^X_a$ for $X \subseteq \mathbb{N}$ and $a \in \mathcal{O}^X$. We note that $\mathsf{ATR}_0$ is equivalent to $\forall X\, \forall a\, (\mathcal{O}(a, X) \rightarrow \mathrm{H}^X_a \text{ exists})$. We prove $\mathsf{ATR}_0$ versions of the major classical results: *invariance of Turing degree* (VIII.3.13); $\Delta^1_1 = \mathrm{HYP}$ (VIII.3.19); the theorem on *hyperarithmetical quantifiers* (VIII.3.20, VIII.3.27). The latter result involves *pseudohierarchies*. An unorthodox feature of our exposition is that we do not use the recursion theorem.

In §VIII.4 we use the machinery of §VIII.3 to study $\omega$-models of the systems $\Delta^1_1$-$\mathsf{CA}_0$, $\Sigma^1_1$-$\mathsf{AC}_0$, and $\Sigma^1_1$-$\mathsf{DC}_0$. We also consider a closely related system known as *weak* $\Sigma^1_1$-$\mathsf{AC}_0$. We show that $\mathrm{HYP} = \{X\colon X \text{ is hyperarithmetical}\}$ is the *minimum $\omega$-model* of each of these four systems. The proof of this result uses $\Pi^1_1$ *uniformization*. Although the main results of classical hyperarithmetical theory are provable in $\mathsf{ATR}_0$ (§VIII.3), the existence of the $\omega$-model HYP is not (remark VIII.4.4). Nevertheless, we show that $\mathsf{ATR}_0$ proves the existence of countable coded $\omega$-models of $\Sigma^1_1$-$\mathsf{AC}_0$ etc. (theorem VIII.4.20). Indeed, $\mathsf{ATR}_0$ proves that HYP is

the intersection of all such $\omega$-models (theorem VIII.4.23). In particular, $\mathsf{ATR}_0$ proves the *consistency of* $\Sigma^1_1$-$\mathsf{AC}_0$ etc.

In §VIII.5 we present two surprising theorems of Friedman which apply to fairly arbitrary $\mathrm{L}_2$-theories $S \supseteq \mathsf{ACA}_0$. They are: (1) If $S$ is recursively axiomatizable and has an $\omega$-model, then so does $S \wedge \neg\exists$ countable coded $\omega$-model of $S$. (2) If $S$ is finitely axiomatizable, then $\Pi^1_\infty$-$\mathsf{TI}_0$ proves $S \to \exists$ a countable coded $\omega$-model of $S$. Note that (1) is an *$\omega$-model incompleteness theorem*, while (2) is an *$\omega$-model reflection principle*. Combining (1) and (2), we see that if $S$ is finitely axiomatizable and has an $\omega$-model, then there exists an $\omega$-model of $S$ which is does not satisfy $\Pi^1_\infty$-$\mathsf{TI}_0$ (corollary VIII.5.8).

At the end of §VIII.5 we prove that $\Pi^1_1$ *transfinite induction* is equivalent to *$\omega$-model reflection for $\Sigma^1_3$ formulas*, which is equivalent to $\Sigma^1_1$ *dependent choice* (theorem VIII.5.12). From this it follows that there exists an $\omega$-model of $\mathsf{ATR}_0$ in which $\Sigma^1_1$-$\mathsf{DC}_0$ fails (theorem VIII.5.13). This is in contrast to the fact that $\mathsf{ATR}_0$ implies $\Sigma^1_1$-$\mathsf{AC}_0$ (theorem V.8.3).

Section VIII.6 presents several *hard core theorems*. We show that any model $M$ of $\mathsf{ATR}_0$ has a proper $\beta$-submodel; indeed, by corollary VIII.6.10, $\mathrm{HYP}^M$ is the intersection of all such submodels. We also prove the following theorem of Quinsey: if $M$ is any $\omega$-model of a recursively axiomatizable $\mathrm{L}_2$-theory $S \supseteq \mathsf{ATR}_0$, then $M$ has a proper submodel which is again a model of $S$ (theorem VIII.6.12). Indeed, $\mathrm{HYP}^M$ is the intersection of all such submodels (exercise VIII.6.23). In particular, no such $S$ has a minimal $\omega$-model.

**Chapter IX: non-$\omega$-models.** In chapter IX we study non-$\omega$-models of various subsystems of $\mathsf{Z}_2$. Section IX.1 deals with $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$. Sections IX.2 and IX.3 are concerned with $\mathsf{WKL}_0$. Section IX.4 is concerned with various systems including $\Pi^1_k$-$\mathsf{CA}_0$ and $\Sigma^1_k$-$\mathsf{AC}_0$, $k \geq 0$. For most of the results of chapter IX, it is essential that our systems contain only restricted induction and not full induction. Many of the results can be phrased as conservation theorems. The methods of §§IX.3 and IX.4 depend crucially on the existence of nonstandard integers.

We begin in §IX.1 by showing that every model $M$ of $\mathsf{PA}$ can be expanded to a model of $\mathsf{ACA}_0$. The expansion is accomplished by letting $\mathcal{S}_M = \mathrm{Def}(M) = \{X \subseteq |M| \colon X$ is first order definable over $M$ allowing parameters from $M\}$. From this it follows that $\mathsf{PA}$ is the first order part of $\mathsf{ACA}_0$, and that $\mathsf{ACA}_0$ has the same consistency strength as $\mathsf{PA}$. We then prove analogous results for $\mathsf{RCA}_0$. Namely, every model $M$ of $\Sigma^0_1$-$\mathsf{PA}$ can be expanded to a model of $\mathsf{RCA}_0$; the expansion is accomplished by letting $\mathcal{S}_M = \Delta^0_1$-$\mathrm{Def}(M) = \{X \subseteq |M| \colon X$ is $\Delta^0_1$ definable over $M$ allowing parameters from $M\}$. The delicate point of this argument is to show that the expansion preserves $\Sigma^0_1$ induction. It follows that $\Sigma^0_1$-$\mathsf{PA}$ is the first order part of $\mathsf{RCA}_0$, and that $\mathsf{RCA}_0$ has the same consistency strength as $\Sigma^0_1$-$\mathsf{PA}$.

In §IX.2 we show that $\mathsf{WKL}_0$ has the same first order part and consistency strength as $\mathsf{RCA}_0$. This is based on the following model-theoretic result due to Harrington: Given a countable model $M$ of $\mathsf{RCA}_0$, we can construct a countable model $M'$ of $\mathsf{WKL}_0$ such that $M$ is an $\omega$-submodel of $M'$. The model $M'$ is obtained from $M$ by iterated forcing, where at each stage we force with trees to add a generic path through a tree. Again, the delicate point is to verify that $\Sigma^0_1$ induction is preserved. This model-theoretic result implies that $\mathsf{WKL}_0$ is conservative over $\mathsf{RCA}_0$ for $\Pi^1_1$ sentences.

In §IX.3 we introduce the well known formal system PRA of *primitive recursive arithmetic*. This theory of primitive recursive functions contains a function symbol and defining axioms for each such function. We prove the following result of Friedman: $\mathsf{WKL}_0$ has the same consistency strength as PRA and is conservative over PRA for $\Pi^0_2$ sentences. Our proof uses a model-theoretic method due to Kirby and Paris, involving *semiregular cuts*. The foundational significance of PRA is that it embodies *Hilbert's concept of finitism*. Therefore, Friedman's theorem combined with the mathematical work of chapters II and IV shows that a significant portion of mathematical practice is finitistically reducible. Thus we have a *partial realization of Hilbert's program*; see also remark IX.3.18.

In §IX.4 we use *recursively saturated models* to prove some surprising conservation theorems for various subsystems of $\mathsf{Z}_2$. The main results may be summarized as follows: For each $k \geq 0$, $\Sigma^1_{k+1}$-$\mathsf{AC}_0$ has the same consistency strength as $\Pi^1_k$-$\mathsf{CA}_0$ and is conservative over $\Pi^1_k$-$\mathsf{CA}_0$ for $\Pi^1_l$ sentences, $l = \min(k+2, 4)$. These results are due to Barwise/Schlipf, Feferman, Friedman, and Sieg. We also obtain a number of related results.

Section IX.5 is a very brief discussion of Gentzen-style proof theory, with emphasis on provable ordinals of subsystems of $\mathsf{Z}_2$.

This completes our summary of Part B.

**Appendix: Chapter X: Additional Results.** Chapter X is an appendix in which some additional Reverse Mathematics results and problems are presented without proof but with references to the published literature.

In §X.1 we consider *measure theory* in subsystems of $\mathsf{Z}_2$. We introduce the formal system $\mathsf{WWKL}_0$ consisting of $\mathsf{RCA}_0$ plus *weak weak König's lemma* and show that it is just strong enough to prove several measure theoretic results, e.g., the *Vitali covering theorem*. We also consider measure theory in stronger systems such as $\mathsf{ACA}_0$.

In §X.2 we mention some additional results on *separable Banach spaces* in subsystems of $\mathsf{Z}_2$. We note that $\mathsf{WKL}_0$ is just strong enough to prove *Banach separation*. We develop various notions related to the *weak-* topology* on $X^*$, the dual of a separable Banach space. We show that $\Pi^1_1$-$\mathsf{CA}_0$ is just strong enough to prove the existence of the *weak-*-closed linear span* of a countable set $Y$ in $X^*$.

In §X.3 we consider *countable combinatorics* in subsystems of $\mathsf{Z}_2$. We note that *Hindman's theorem* lies between $\mathsf{ACA}_0$ and a slightly stronger system, $\mathsf{ACA}_0^+$. We mention a similar result for the closely related *Auslander/Ellis theorem* of topological dynamics. In the area of *matching theory*, we show that the *Podewski/Steffens theorem* ("every countable bipartite graph has a König covering") is equivalent to $\mathsf{ATR}_0$. At the end of the section we consider *well quasiordering theory*, noting for instance that the *Nash-Williams transfinite sequence theorem* lies between $\mathsf{ATR}_0$ and $\Pi^1_1$-$\mathsf{CA}_0$.

In §X.4 we initiate a project of weakening the base theory for Reverse Mathematics. We introduce a system $\mathsf{RCA}_0^*$ which is essentially $\mathsf{RCA}_0$ with $\Sigma^0_1$ induction weakened to $\Sigma^0_0$ induction. We also introduce a system $\mathsf{WKL}_0^*$ consisting of $\mathsf{RCA}_0^*$ plus weak König's lemma. We present some conservation results showing in particular that $\mathsf{RCA}_0^*$ and $\mathsf{WKL}_0^*$ have the same consistency strength as $\mathsf{EFA}$, elementary function arithmetic. We note that several theorems of countable algebra are equivalent over $\mathsf{RCA}_0^*$ to $\Sigma^0_1$ induction. Among these are: (1) every polynomial over a countable field has an irreducible factor; (2) every finitely generated vector space over $\mathbb{Q}$ has a basis.

## I.14. Conclusions

In this chapter we have presented and motivated the main themes of the book, including the Main Question (§§I.1, I.12) and Reverse Mathematics (§I.9). A detailed outline of the book is in section I.13. The five most important subsystems of second order arithmetic are $\mathsf{RCA}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$, $\Pi^1_1$-$\mathsf{CA}_0$. Part A of the book consists of chapters II through VI and focuses on the development of mathematics in these five systems. Part B consists of chapters VII through IX and focuses on models of these and other subsystems of $\mathsf{Z}_2$. Additional results are presented in an appendix, chapter X.

# Part A

# DEVELOPMENT OF MATHEMATICS WITHIN SUBSYSTEMS OF $Z_2$

Chapter II

# RECURSIVE COMPREHENSION

## II.1. The Formal System $\mathsf{RCA}_0$

The purpose of this chapter is to study a certain subsystem of second order arithmetic known as $\mathsf{RCA}_0$. $\mathsf{RCA}_0$ is the weakest subsystem of $\mathsf{Z}_2$ to be studied extensively in this book. It will play a key role in chapters III through VI as the "weak base theory" for Reverse Mathematics.

The acronym RCA stands for "recursive comprehension axiom." Roughly speaking, the set existence axioms of $\mathsf{RCA}_0$ are only strong enough to prove the existence of recursive sets of natural numbers. However, these axioms do not rule out the existence of nonrecursive sets of natural numbers.

The purpose of this section is to present the axioms of $\mathsf{RCA}_0$ and characterize the $\omega$-models of $\mathsf{RCA}_0$. In the rest of the chapter, we shall show that certain portions of ordinary mathematics can be developed within $\mathsf{RCA}_0$. Some further results on models of $\mathsf{RCA}_0$ will be presented in chapters VIII and IX.

In order to state the axioms of $\mathsf{RCA}_0$ we shall need some definitions.

Definition II.1.1. Let $\varphi$ be a formula of $\mathrm{L}_2$, let $n$ be a number variable, and let $t$ be a numerical term which does not contain $n$. We abbreviate $\forall n\,(n < t \to \varphi)$ as $(\forall n < t)\,\varphi$. We abbreviate $\exists n\,(n < t \wedge \varphi)$ as $(\exists n < t)\,\varphi$. The quantifiers $\forall n < t$ and $\exists n < t$ are known as *bounded quantifiers*.

Definition II.1.2. An $\mathrm{L}_2$-formula is said to be $\Sigma^0_0$ if it is built up from atomic formulas by means of propositional connectives and bounded number quantifiers. For $k \in \omega$, an $\mathrm{L}_2$-formula is said to be $\Sigma^0_k$ (respectively $\Pi^0_k$) if it is of the form $\exists n_1\, \forall n_2 \cdots n_k\, \theta$ (respectively $\forall n_1\, \exists n_2 \cdots n_k\, \theta$) where $\theta$ is $\Sigma^0_0$.

In particular, a $\Sigma^0_1$ (respectively $\Pi^0_1$) formula is one of the form $\exists n\, \theta$ (respectively $\forall n\, \theta$) where $\theta$ is $\Sigma^0_0$. Note that although $\Sigma^0_k$ and $\Pi^0_k$ formulas contain no set quantifiers, they may contain free set variables.

Definition II.1.3. For each $k \in \omega$, the scheme of $\Sigma^0_k$ *induction* consists of all axioms of the form

$$(\varphi(0) \wedge \forall n\,(\varphi(n) \to \varphi(n+1))) \to \forall n\,\varphi(n)$$

where $\varphi(n)$ is any $\Sigma^0_k$ formula of the language of second order arithmetic. The scheme of $\Pi^0_k$ *induction* is defined similarly.

Definition II.1.4. The scheme of $\Delta^0_1$ *comprehension* consists of all axioms of the form

$$\forall n\,(\varphi(n) \leftrightarrow \psi(n)) \to \exists X\,\forall n\,(n \in X \leftrightarrow \varphi(n))$$

where $\varphi(n)$ is $\Sigma^0_1$, $\psi(n)$ is $\Pi^0_1$, and $X$ is not free in $\varphi(n)$.

We are now ready to define $\mathsf{RCA}_0$.

Definition II.1.5. $\mathsf{RCA}_0$ is the formal system in the language $\mathrm{L}_2$ whose axioms consist of the basic axioms (see definition I.2.4(i)) plus the schemes of $\Sigma^0_1$ induction and $\Delta^0_1$ comprehension.

We now characterize the $\omega$-models of $\mathsf{RCA}_0$. We assume familiarity with the elements of recursive function theory (see e.g., Davis [44] or Rogers [208] or Cutland [43]).

Lemma II.1.6. *Let $X$ and $Y$ be subsets of $\omega$. The following are equivalent.*

(i) *$X$ is recursively enumerable in $Y$;*
(ii) *$X$ is definable (in the intended model of second order arithmetic) by a $\Sigma^0_1$ formula with parameter $Y$.*

Proof. This is immediate from any one of several familiar characterizations of "recursively enumerable in". □

Theorem II.1.7. *Let $\mathcal{S}$ be a collection of subsets of $\omega$. $\mathcal{S}$ is an $\omega$-model of $\mathsf{RCA}_0$ if and only if $\mathcal{S}$ enjoys the following closure properties:*

(i) *$\mathcal{S}$ is nonempty;*
(ii) *if $X, Y \in \mathcal{S}$, then $X \oplus Y \in \mathcal{S}$ where*

$$X \oplus Y = \{2n : n \in X\} \cup \{2n+1 : n \in Y\};$$

(iii) *if $X \leq_{\mathrm{T}} Y$ and $Y \in \mathcal{S}$, then $X \in \mathcal{S}$. Here $\leq_{\mathrm{T}}$ denotes Turing reducibility, i.e., $X \leq_{\mathrm{T}} Y$ if and only if $X$ is recursive in $Y$.*

(See also §§VII.1 and VIII.1.)

Proof. Lemma II.1.6 implies that $X \leq_{\mathrm{T}} (Y_1 \oplus \cdots \oplus Y_n)$ if and only if both $X$ and $\omega \setminus X$ are definable by $\Sigma^0_1$ formulas with parameters $Y_1, \ldots, Y_n$. From this the theorem follows easily. □

Remark. Collections $\mathcal{S} \subseteq P(\omega)$ satisfying (i), (ii) and (iii) are known as *Turing ideals*. Such collections have been studied extensively in the literature on degrees of unsolvability.

Corollary II.1.8. *The minimum $\omega$-model of* $\mathsf{RCA}_0$ *is the collection*

$$\mathrm{REC} = \{X \subseteq \omega : X \text{ is recursive}\}.$$

For more information on models of $\mathsf{RCA}_0$, see chapters VIII and IX.

**Notes for §II.1.** The system $\mathsf{RCA}_0$ is due to Friedman [69]. Actually Friedman's axiomatization of $\mathsf{RCA}_0$ is somewhat different from the one used here. For a thorough introduction to recursive function theory, see Davis [44] and Rogers [208]. For a survey of results on degrees of unsolvability, see Simpson [231].

## II.2. Finite Sequences

It is well known that finite sequences of natural numbers can be encoded as single natural numbers. The purpose of this section is to show that one such coding method can be developed formally within $\mathsf{RCA}_0$.

We begin with some elementary properties of the natural numbers. Within $\mathsf{RCA}_0$ we define $\mathbb{N}$ to be the set of all natural numbers, i.e., the unique set $X$ such that $\forall n\,(n \in X)$. The following lemma can be summarized by saying that the natural number system $\mathbb{N}, +, \cdot, 0, 1, <$ is a commutative ordered semiring with cancellation.

Lemma II.2.1. *The following are provable in* $\mathsf{RCA}_0$.

(i) $(m + n) + p = m + (n + p)$
(ii) $0 + m = m$
(iii) $1 + m = m + 1$
(iv) $m + n = n + m$
(v) $m \cdot (n + p) = m \cdot n + m \cdot p$
(vi) $(m \cdot n) \cdot p = m \cdot (n \cdot p)$
(vii) $(m + n) \cdot p = m \cdot p + n \cdot p$
(viii) $0 \cdot m = 0$
(ix) $1 \cdot m = m$
(x) $m \cdot n = n \cdot m$
(xi) $(m < n \wedge n < p) \to m < p$
(xii) $m < n \to m + 1 < n + 1$
(xiii) $m + 1 < n + 1 \to m < n$
(xiv) $n \neq 0 \to 0 < n$
(xv) $m < n \vee m = n \vee n < m$
(xvi) $\neg n < n$
(xvii) $m < n \to m + p < n + p$
(xviii) $m + p < n + p \to m < n$
(xix) $m < m + n + 1$
(xx) $m + p = n + p \to m = n$
(xxi) $(p \neq 0 \wedge m < n) \to m \cdot p < n \cdot p$
(xxii) $(p \neq 0 \wedge m \cdot p < n \cdot p) \to m < n$

(xxiii) $(p \neq 0 \wedge m \cdot p = n \cdot p) \rightarrow m = n$
(xxiv) $m < n \rightarrow (\exists k < n)\, m + k + 1 = n$
(xxv) $n \neq 0 \rightarrow (\exists m < n)\, m + 1 = n$.

PROOF. Each of statements (i)–(xxiii) is proved by a straightforward induction on the alphabetically last variable occurring in the statement. Previous statements may be used in the base step or the successor step. For example, here is the proof of (x) $m \cdot n = n \cdot m$. We proceed by induction on $n$. For $n = 0$ we have, using (viii) and one of the basic axioms, $m \cdot 0 = 0 = 0 \cdot m$. For $n + 1$ we have, using the induction hypothesis $m \cdot n = n \cdot m$ as well as (ix) and (vii) and one of the basic axioms, $m \cdot (n+1) = m \cdot n + m = n \cdot m + m = n \cdot m + 1 \cdot m = (n+1) \cdot m$. By induction on $n$ it follows that $m \cdot n = n \cdot m$ for all $n$. (It is interesting to note that only quantifier-free induction is used in the proofs of (i)–(xxiii).)

We now prove (xxiv) by induction on $n$. For $n = 0$, we have by one of the basic axioms $\neg m < 0$ so there is nothing to prove. For $n + 1$, if $m < n + 1$ then by one of the basic axioms, either $m < n$ or $m = n$. If $m < n$ it follows by induction that $m + k + 1 = n$ for some $k < n$. Hence $m + (k + 1) + 1 = n + 1$ and by (xii) we have $k + 1 < n + 1$. If $m = n$ then $m + 0 + 1 = n + 1$ and by (xiv) and one of the basic axioms we have $0 < n + 1$. Statement (xxiv) follows by $\Sigma^0_0$ induction. Statement (xxv) is a special case of (xxiv) in view of (xiv). This completes the proof of lemma II.2.1. □

Within $\mathsf{RCA}_0$ we define a *pairing map*

$$(i, j) = (i + j)^2 + i$$

where of course $k^2 = k \cdot k$. Part 2 of the following theorem says that the pairing map is a one-to-one mapping of $\mathbb{N} \times \mathbb{N}$ into $\mathbb{N}$.

THEOREM II.2.2. *The following are provable in* $\mathsf{RCA}_0$.

1. $i \leq (i, j)$ *and* $j \leq (i, j)$.
2. $(i, j) = (i', j') \rightarrow (i = i' \wedge j = j')$.

PROOF. Part 1 is obvious from II.2.1(xix). For part 2, given $k = (i, j) = (i + j)^2 + i$, we claim that there exists a unique $m$ such that $m^2 \leq k < (m + 1)^2$. Existence of $m$ is obvious by taking $m = i + j$, and uniqueness follows from the fact that $m < n \rightarrow m^2 < n^2$. It now follows that $i = k - m^2$ and $j = m - i$. This proves part 2. □

Our next goal is to show that finite sets of natural numbers can be encoded as single natural numbers. This requires us to develop a little bit of elementary number theory within $\mathsf{RCA}_0$.

From now on we write $mn = m \cdot n$. We say that $m$ *divides* $n$ (written $m \mid n$) if $\exists q\, (mq = n)$. For $m_1$ and $m_2$ both nonzero, we say that $m_1$ *is prime relative to* $m_2$ if $\forall n\, (m_2 \mid m_1 n \rightarrow m_2 \mid n)$.

LEMMA II.2.3. *The following is provable in* $\mathsf{RCA}_0$. *If* $m_1$ *is prime relative to* $m_2$ *then* $m_2$ *is prime relative to* $m_1$.

PROOF. Assume that $m_1$ is prime relative to $m_2$. Let $n$ be given such that $m_1 \mid m_2 n$. Let $q$ be such that $m_1 q = m_2 n$. Then $m_2 \mid m_1 q$. Since $m_1$ is prime relative to $m_2$ it follows that $m_2 \mid q$. Let $r$ be such that $m_2 r = q$. Then $m_1 m_2 r = m_1 q = m_2 n$. Hence $m_1 r = n$. So $m_1 \mid n$. This completes the proof. □

LEMMA II.2.4. *The following is provable in* $\mathsf{RCA}_0$. (i) *Given* $k$, *there exists* $m > 0$ *such that* $\forall i < k\ (i+1$ *divides* $m)$. (ii) *Let* $k$ *and* $m$ *be as in part* (i). *Then* $m(i+1)+1$ *and* $m(j+1)+1$ *are relatively prime to each other for all* $i < j < k$.

PROOF. Part (i) is easily proved by $\Sigma^0_1$ induction on $k$. For part (ii) let $i < j < k$ be given. We shall show that $m(j+1)+1$ is prime relative to $m(i+1)+1$. First note that for all $n$, if $m$ divides $m(i+1)n + n$ then $m$ divides $n$. Thus $m(i+1)+1$ is prime relative to $m$. Hence by lemma II.2.3, $m$ is prime relative to $m(i+1)+1$. Now let $n$ be given such that $m(i+1)+1$ divides $(m(j+1)+1)n$. Let $l$ be such that $i+l+1 = j$. Then $(m(j+1)+1)n = (m(i+l+1+1)+1)n = (m(i+1)+1)n + m(l+1)n$. Therefore $m(i+1)+1$ divides $m(l+1)n$. Since $m$ is prime relative to $m(i+1)+1$ it follows that $m(i+1)+1$ divides $(l+1)n$. Since $l+1$ divides $m$ it follows that $m(i+1)+1$ divides $mn$. Using again the fact that $m$ is prime relative to $m(i+1)+1$, we see that $m(i+1)+1$ divides $n$. This completes the proof that $m(j+1)+1$ is prime relative to $m(i+1)+1$. It follows by lemma II.2.3 that $m(i+1)+1$ is prime relative to $m(j+1)+1$. This completes the proof. □

Within $\mathsf{RCA}_0$ we define a *finite set* to be a set $X$ such that $\exists k\, \forall i\, (i \in X \to i < k)$. We now show that finite sets can be encoded as natural numbers.

THEOREM II.2.5. *The following is provable in* $\mathsf{RCA}_0$. *For any finite set* $X \subseteq \mathbb{N}$ *there exist* $k$, $m$ *and* $n \in \mathbb{N}$ *such that*

$$\forall i\, (i \in X \leftrightarrow (i < k \wedge m(i+1)+1 \text{ divides } n)). \tag{3}$$

The least number of the form $(k,(m,n))$ such that (3) holds is called the *code* of the finite set $X$. Thus each finite set of natural numbers has a unique code. This fact is extremely important.

PROOF. Let $k$ be such that $\forall i\, (i \in X \to i < k)$. By II.2.4 let $m$ be such that the numbers $m(i+1)+1$ for $i < k$ are pairwise relatively prime. Let $\varphi(j)$ be a $\Sigma^0_1$ formula asserting that either $j > k$ or $\exists n\, \forall i < k\ (m(i+1)+1$ divides $n \leftrightarrow (i \in X \wedge i < j))$. We prove $\forall j\, \varphi(j)$ by induction on $j$. For $j = 0$ or $j > k$ there is nothing to prove. For $j' = j+1 \le k$ put $n' = n(m(j+1)+1)$ if $j \in X$, $n' = n$ if $j \notin X$. Then for each $i < k$ we see that $m(i+1)+1$ divides $n'$ if and only if either $i = j \in X$ or $m(i+1)+1$ divides $n$. Hence by the induction hypothesis it follows that $\forall i < k\ (m(i+1)+1$ divides $n' \leftrightarrow (i \in X \wedge i < j+1))$. This proves $\forall j\, \varphi(j)$. From $\varphi(k)$ we have the conclusion of the theorem. □

We can now present our coding method for finite sequences of natural numbers.

DEFINITION II.2.6. The following definitions are made in $\mathsf{RCA}_0$. A *finite sequence of natural numbers* is a finite set $X$ such that $\forall n\,(n \in X \to \exists i\,\exists j\,(n = (i,j)))$ and $\forall i\,\forall j\,\forall k\,(((i,j) \in X \wedge (i,k) \in X) \to j = k)$ and $\exists l\,\forall i\,(i < l \leftrightarrow \exists j\,((i,j) \in X))$. Here $(i,j)$ denotes the pairing map of theorem II.2.2. The number $l$ is uniquely determined and is called the *length* of $X$. The *code* of the finite sequence $X$ is just the code of $X$ as a finite set (theorem II.2.5).

The set of all codes of finite sequences is denoted Seq or $\mathbb{N}^{<\mathbb{N}}$. This set exists by $\Sigma^0_0$ comprehension. If $s \in \mathrm{Seq}$ is the code of the finite sequence $X$, we write $\mathrm{lh}(s)$ for the length of $X$, and if $i < \mathrm{lh}(s)$ we write $s(i)$ for the unique $j$ such that $(i,j) \in X$. We shall sometimes use notations such as

$$s = \langle s(0), s(1), \ldots, s(\mathrm{lh}(s) - 1)\rangle$$

or

$$s = \langle s(i) \colon i < \mathrm{lh}(s)\rangle.$$

Whenever convenient we shall identify a finite sequence of natural numbers with its code.

If $s, t \in \mathrm{Seq}$ we denote *concatenation* by $^\frown$, i.e.,

$$s^\frown t = \langle s(0), \ldots, s(\mathrm{lh}(s) - 1), t(0), \ldots, t(\mathrm{lh}(t) - 1)\rangle$$

so that $\mathrm{lh}(s^\frown t) = \mathrm{lh}(s) + \mathrm{lh}(t)$. In particular

$$s^\frown\langle n\rangle = \langle s(0), \ldots, s(\mathrm{lh}(s) - 1), n\rangle$$

and $\mathrm{lh}(s^\frown\langle n\rangle) = \mathrm{lh}(s) + 1$. We write $s \subseteq t$ to mean that $s$ is an *initial segment* of $t$, i.e., $\mathrm{lh}(s) \leq \mathrm{lh}(t) \wedge (\forall i < \mathrm{lh}(s))\, s(i) = t(i)$. Note that the predicates $\mathrm{lh}(s) = m$, $s(i) = n$, $s \subseteq t$, $s^\frown\langle n\rangle = t$, etc., are $\Sigma^0_0$.

We state here the following formal version of the well known *Kleene normal form theorem* for $\Sigma^0_1$ relations. This result will be used several times.

THEOREM II.2.7 (normal form theorem). *Let $\varphi(X)$ be a $\Sigma^0_1$ formula. Then we can find a $\Sigma^0_0$ formula $\theta(s)$ such that $\mathsf{RCA}_0$ proves*

$$\forall X\,(\varphi(X) \leftrightarrow \exists m\,\theta(X[m])).$$

Here we write $X[m] = \langle \xi_0, \xi_1, \ldots, \xi_{m-1}\rangle$ where $\xi_i = 1$ if $i \in X$, $0$ if $i \notin X$. Thus $X[m]$ is the finite initial sequence of length $m$ of the characteristic function of $X$. Note that $\varphi(X)$ may contain free variables other than $X$. If this is the case, then $\theta(s)$ will also contain those free variables.

PROOF. The proof is obtained by straightforwardly formalizing the Kleene normal form theorem in $\mathsf{RCA}_0$, using the methods of §II.3. See also Kleene [142] or Rogers [208]. See also the last part of the proof of lemma IX.2.4 below. □

**Notes for §II.2.** Our method of encoding finite sequences (II.2.5, II.2.6) is adapted from Shoenfield [222, page 115].

## II.3. Primitive Recursion

In this section we prove within $\mathsf{RCA}_0$ that the universe of total number-theoretic functions is closed under composition, primitive recursion, and the least number operator. As an application of these results we show that the $\Sigma^0_1$ induction scheme of $\mathsf{RCA}_0$ is equivalent to a certain set existence principle known as bounded $\Sigma^0_1$ comprehension.

Definition II.3.1 (functions). The following definitions are made in $\mathsf{RCA}_0$. Let $X$ and $Y$ be sets of natural numbers. We write $X \subseteq Y$ to mean $\forall n\,(n \in X \to n \in Y)$. We define $X \times Y$ to be the set of all $k$ such that $\exists i \le k\, \exists j \le k\, (i \in X \wedge j \in Y \wedge (i,j) = k)$. This set exists by $\Sigma^0_0$ comprehension; $(i,j)$ denotes the pairing map of theorem II.2.2. We define a function $f\colon X \to Y$ to be a set $f \subseteq X \times Y$ such that $\forall i\, \forall j\, \forall k\, (((i,j) \in f \wedge (i,k) \in f) \to j = k)$ and $\forall i\, \exists j\, (i \in X \to (i,j) \in f)$. If $f\colon X \to Y$ and $i \in X$ we denote by $f(i)$ the unique $j$ such that $(i,j) \in f$.

Theorem II.3.2 (composition). *The following is provable in* $\mathsf{RCA}_0$. *If* $f\colon X \to Y$ *and* $g\colon Y \to Z$ *then there exists* $h = gf\colon X \to Z$ *defined by* $h(i) = g(f(i))$.

Proof. We have $\exists j\, ((i,j) \in f \wedge (j,k) \in g) \leftrightarrow (i \in X \wedge \forall j\, ((i,j) \in f \to (j,k) \in g))$. Hence by $\Delta^0_1$ comprehension there exists $h$ such that $(i,k) \in h \leftrightarrow \exists j\, ((i,j) \in f \wedge (j,k) \in g)$. Clearly $h = gf$. □

Definition II.3.3. The following definitions are made in $\mathsf{RCA}_0$. The set of all $s \in \mathrm{Seq}$ such that $\mathrm{lh}(s) = k$ is denoted $\mathbb{N}^k$. This set exists by $\Sigma^0_0$ comprehension. If $f\colon \mathbb{N}^k \to \mathbb{N}$ and $s = \langle n_1, \ldots, n_k \rangle \in \mathbb{N}^k$, we sometimes write $f(n_1, \ldots, n_k)$ instead of $f(s)$.

The above definition permits us to discuss $k$-ary functions $f\colon \mathbb{N}^k \to \mathbb{N}$ for variable $k \in \mathbb{N}$, within $\mathsf{RCA}_0$. We can also discuss finite sequences $\langle f_1, \ldots, f_m \rangle$ of $k$-ary functions $f_i\colon \mathbb{N}^k \to \mathbb{N}$, $1 \le i \le m$. Such a sequence is identified in the obvious way with a single function $f\colon \mathbb{N}^k \to \mathbb{N}^m$. Thus theorem II.3.2 implies that the universe of functions is closed under generalized composition, i.e., given $f_i\colon \mathbb{N}^k \to \mathbb{N}$, $1 \le i \le m$, and $g\colon \mathbb{N}^m \to \mathbb{N}$, there exists $h\colon \mathbb{N}^k \to \mathbb{N}$ defined by $h(n_1, \ldots, n_k) = g(f_1(n_1, \ldots, n_k), \ldots, f_m(n_1, \ldots, n_k))$.

The next theorem says that the universe of $k$-ary functions, $k \in \mathbb{N}$, is closed under *primitive recursion*.

Theorem II.3.4 (primitive recursion). *The following is provable in* $\mathsf{RCA}_0$. *Given* $f\colon \mathbb{N}^k \to \mathbb{N}$ *and* $g\colon \mathbb{N}^{k+2} \to \mathbb{N}$, *there exists a unique* $h\colon \mathbb{N}^{k+1} \to \mathbb{N}$

*defined by*

$$h(0, n_1, \ldots, n_k) = f(n_1, \ldots, n_k),$$
$$h(m+1, n_1, \ldots, n_k) = g(h(m, n_1, \ldots, n_k), m, n_1, \ldots, n_k).$$

PROOF. Let $\theta(s, m, \langle n_1, \ldots, n_k\rangle)$ say that $s \in \mathrm{Seq}$ and $\mathrm{lh}(s) = m+1$ and $s(0) = f(n_1, \ldots, n_k)$ and, for all $i < m$, $s(i+1) = g(s(i), i, n_1, \ldots, n_k)$. The formula $\exists s\, \theta(s, m, \langle n_1, \ldots, n_k\rangle)$ is $\Sigma^0_1$ so for each fixed $\langle n_1, \ldots, n_k\rangle \in \mathbb{N}^k$ we can prove this formula by the obvious $\Sigma^0_1$ induction on $m$. Also, if $\theta(s, m, \langle n_1, \ldots, n_k\rangle)$ and $\theta(s', m, \langle n_1, \ldots, n_k\rangle)$ then we can prove $s(i) = s'(i)$ by induction on $i < m+1$. It follows that for all $\langle n_1, \ldots, n_k\rangle \in \mathbb{N}^k$ and all $m$ and $j$,

$$\exists s\, (\theta(s, m, \langle n_1, \ldots, n_k\rangle) \wedge s(m) = j) \leftrightarrow \forall s\, (\theta(s, m, \langle n_1, \ldots, n_k\rangle) \rightarrow s(m) = j).$$

Hence by $\Delta^0_1$ comprehension there exists $h : \mathbb{N}^{k+1} \to \mathbb{N}$ such that

$$h(m, n_1, \ldots, n_k) = j$$

if and only if $\exists s\, (\theta(s, m, \langle n_1, \ldots, n_k\rangle) \wedge s(m) = j)$. Clearly $h$ has the desired properties. □

Next we show that the universe of functions is closed under the *least number operator*, i.e., *minimization*.

THEOREM II.3.5 (minimization). *The following is provable in* $\mathsf{RCA}_0$. *Let* $f : \mathbb{N}^{k+1} \to \mathbb{N}$ *be such that for all* $\langle n_1, \ldots, n_k\rangle \in \mathbb{N}^k$ *there exists* $m \in \mathbb{N}$ *such that* $f(m, n_1, \ldots, n_k) = 1$. *Then there exists* $g : \mathbb{N}^k \to \mathbb{N}$ *defined by* $g(n_1, \ldots, n_k) =$ *least* $m$ *such that* $f(m, n_1, \ldots, n_k) = 1$.

PROOF. By $\Sigma^0_0$ comprehension there exists $g \subseteq \mathbb{N}^k \times \mathbb{N}$ such that

$$(\langle n_1, \ldots, n_k\rangle, m) \in g$$

if and only if $(\langle m, n_1, \ldots, n_k\rangle, 1) \in f \wedge \neg(\exists j < m)\, (\langle j, n_1, \ldots, n_k\rangle, 1) \in f$. The hypothesis of the theorem implies that $g : \mathbb{N}^k \to \mathbb{N}$ and clearly $g$ has the desired property. □

We now present some important consequences of the above results.

LEMMA II.3.6. *The following is provable in* $\mathsf{RCA}_0$. *For any infinite set* $X \subseteq \mathbb{N}$, *there exists a function* $\pi_X : \mathbb{N} \to \mathbb{N}$ *such that* $\forall k\, \forall m\, (k < m \rightarrow \pi_X(k) < \pi_X(m))$ *and* $\forall n\, (n \in X \leftrightarrow \exists m\, (\pi_X(m) = n))$.

PROOF. First define $v_X : \mathbb{N} \to \mathbb{N}$ by $v_X(m) =$ least $n$ such that $n \in X$ and $n \geq m$. Then use primitive recursion (theorem II.3.4) to define $\pi_X : \mathbb{N} \to \mathbb{N}$ by $\pi_X(0) = v_X(0)$, $\pi_X(m+1) = v_X(\pi_X(m)+1)$. Using $\Sigma^0_0$ induction it follows easily that $k < m \rightarrow \pi_X(k) < \pi_X(m)$ and $n \in X \rightarrow (\exists m \leq n)\, \pi_X(m) = n$. □

The next lemma is analogous to the well known fact that an infinite recursively enumerable set is the range of a one-to-one recursive function.

LEMMA II.3.7. *Let $\varphi(n)$ be a $\Sigma^0_1$ formula in which $X$ and $f$ do not occur freely. The following is provable in* $\mathsf{RCA}_0$. *Either there exists a finite set $X$ such that $\forall n\,(n \in X \leftrightarrow \varphi(n))$, or there exists a one-to-one function $f : \mathbb{N} \to \mathbb{N}$ such that $\forall n\,(\varphi(n) \leftrightarrow \exists m\,(f(m) = n))$.*

PROOF. Suppose that the first alternative fails. Write $\varphi(n)$ as $\exists j\,\theta(j,n)$ where $\theta(j,n)$ is $\Sigma^0_0$. By $\Sigma^0_0$ comprehension let $Y$ be the set of all $(j,n)$ such that $\theta(j,n) \wedge \neg(\exists i < j)\,\theta(i,n)$. Since the first alternative fails, $Y$ is infinite. Hence by lemma II.3.6 let $\pi_Y : \mathbb{N} \to \mathbb{N}$ be the function which enumerates the elements of $Y$ in strictly increasing order. By $\Sigma^0_0$ comprehension let $p_2 : \mathbb{N} \to \mathbb{N}$ be the *second projection function*, i.e., $p_2((j,n)) = n$ for all $j, n \in \mathbb{N}$. Let $f : \mathbb{N} \to \mathbb{N}$ be the composition defined by $f(m) = p_2(\pi_Y(m))$. The definition of $Y$ implies that $f$ is one-to-one, and clearly $f$ enumerates exactly those $n \in \mathbb{N}$ such that $\varphi(n)$. This completes the proof. □

DEFINITION II.3.8 (bounded $\Sigma^0_k$ comprehension). For each $k \in \omega$ the scheme of *bounded $\Sigma^0_k$ comprehension* consists of all axioms of the form

$$\forall n\,\exists X\,\forall i\,(i \in X \leftrightarrow (i < n \wedge \varphi(i)))$$

where $\varphi(i)$ is any $\Sigma^0_k$ formula in which $X$ does not occur freely.

THEOREM II.3.9. $\mathsf{RCA}_0$ *proves bounded $\Sigma^0_1$ comprehension*.

PROOF. We reason in $\mathsf{RCA}_0$. Let $\varphi(i)$ be a $\Sigma^0_1$ formula in which $X$ does not occur freely. Given $n$, suppose there is no finite set $X$ such that $\forall i\,(i \in X \leftrightarrow (i < n \wedge \varphi(i)))$. Then by lemma II.3.7 there exists a one-to-one function $f : \mathbb{N} \to \mathbb{N}$ such that $\forall m\,(f(m) < n \wedge \varphi(f(m)))$. In particular the restriction of $f$ to $\{0, \ldots, n-1, n\}$ is a finite one-to-one function from $\{0, \ldots, n-1, n\}$ into $\{0, \ldots, n-1\}$. But it is easy to prove (by $\Sigma^0_0$ induction on the codes of finite functions) that no finite function can have the mentioned properties. This contradiction completes the proof. □

COROLLARY II.3.10. $\mathsf{RCA}_0$ *proves the $\Pi^0_1$ induction scheme*

$$(\psi(0) \wedge \forall n\,(\psi(n) \to \psi(n+1))) \to \forall n\,\psi(n)$$

*where $\psi(n)$ is any $\Pi^0_1$ formula.*

PROOF. Reasoning within $\mathsf{RCA}_0$, assume the hypothesis. Fix $n$. We must show that $\psi(n)$ holds. By bounded $\Sigma^0_1$ comprehension (theorem II.3.9) using $n$ as a parameter, let $X$ be such that $\forall m\,(m \in X \leftrightarrow (m \leq n \wedge \neg\psi(m)))$. By $\Delta^0_1$ comprehension let $Y$ be such that $\forall m\,(m \in Y \leftrightarrow m \notin X)$. By assumption we have $0 \in Y$ and $\forall m\,(m \in Y \to m+1 \in Y)$. Hence by the induction axiom I.2.4(ii) we have $\forall m\,(m \in Y)$, in particular $n \in Y$. Hence $\psi(n)$ holds. This completes the proof. □

REMARK II.3.11. In chapter I we emphasized the role of set existence axioms. It is therefore interesting to note that, despite appearances, the $\Sigma^0_1$

induction axiom of $\mathsf{RCA}_0$ can be considered to be a set existence axiom. Namely, $\Sigma^0_1$ induction is provably equivalent to bounded $\Sigma^0_1$ comprehension (in the presence of the basic axioms, the induction axiom, and $\Delta^0_1$ comprehension).

[One half of this equivalence has already been established as theorem II.3.9. The other half is easily proved, as follows. Given $\varphi(0)\wedge\forall n\,(\varphi(n)\rightarrow\varphi(n+1))$ where $\varphi(n)$ is $\Sigma^0_1$, fix $n$ and apply bounded $\Sigma^0_1$ comprehension to get a set $X$ such that $\forall m\leq n\,(m\in X\leftrightarrow\varphi(m))$. Then apply $\Sigma^0_0$ comprehension to get a set $Y$ such that $\forall m\,(m\in Y\leftrightarrow(m\in X\vee m>n))$. Clearly $0\in Y\wedge\forall m\,(m\in Y\rightarrow m+1\in Y)$. Hence by the induction axiom $\forall m\,(m\in Y)$. In particular $n\in Y$ so $\varphi(n)$ holds. Since $n$ is arbitrary we have we have $\forall n\,\varphi(n)$. See also Simpson/Smith [250, lemma 2.5] and remark X.4.3.]

EXERCISE II.3.12. Show that, for each $k\in\omega$, $\mathsf{RCA}_0$ proves

$$\Sigma^0_k \text{ induction}\leftrightarrow\Pi^0_k \text{ induction}.$$

EXERCISE II.3.13. Show that, for each $k\in\omega$, $\mathsf{RCA}_0$ proves

$$\Sigma^0_k \text{ induction}\leftrightarrow \text{bounded } \Sigma^0_k \text{ comprehension}.$$

EXERCISE II.3.14. Show that $\mathsf{RCA}_0$ proves the *strong* $\Sigma^0_1$ *bounding scheme*:

$$\forall m\,\exists n\,\forall i<m\,((\exists j\,\varphi(i,j))\rightarrow(\exists j<n)\,\varphi(i,j))$$

where $\varphi(i,j)$ is any $\Sigma^0_1$ formula in which $n$ does not occur freely.

EXERCISE II.3.15. For each $k\in\omega$, define the *strong* $\Sigma^0_k$ *bounding principle* (in analogy with the previous exercise) and show that $\mathsf{RCA}_0$ proves

$$\Sigma^0_k \text{ induction}\leftrightarrow \text{strong } \Sigma^0_k \text{ bounding}.$$

REMARK II.3.16. The main focus of this section has been our basic result on primitive recursion, theorem II.3.4. From the viewpoint of ordinary mathematics, the most important consequence of theorem II.3.4 is that *elementary number theory can be developed straightforwardly within* $\mathsf{RCA}_0$. For instance, we can use theorem II.3.4 to prove the existence of the exponential function $f(m,n)=m^n$ defined by $f(m,0)=1$, $f(m,n+1)=f(m,n)\cdot m$. We can then show that $\mathsf{RCA}_0$ proves basic properties such as $(m_1m_2)^n=m_1^nm_2^n$, $m^{n_1+n_2}=m^{n_1}m^{n_2}$, $m^{n_1n_2}=(m^{n_1})^{n_2}$. Also within $\mathsf{RCA}_0$ we can straightforwardly state and prove fundamental results such as unique prime power factorization.

It appears that even the most intricate arguments of elementary number theory, finite combinatorics, and finite group theory can be transcribed into $\mathsf{RCA}_0$. This holds so long as the arguments in question make no essential use of infinite sets. Indeed, such arguments can usually be developed within the much weaker theory $\mathsf{EFA}$ consisting of $\Sigma^0_0$ comprehension, the induction axiom, and the basic axioms augmented by $m^0=1$,

$m^{n+1} = m^n \cdot m$ where now exponentiation is treated as a primitive binary operation symbol.

In the rest of this chapter we shall turn to infinitary mathematics. We shall show that certain elementary portions of the theory of continuous functions, countable algebra, and mathematical logic can be developed within $\mathsf{RCA}_0$.

**Notes for §II.3.** Friedman's original axiomatization of $\mathsf{RCA}_0$ [69] was based on primitive recursion rather than $\Sigma^0_1$ induction. The results of this section are essentially due to Friedman (unpublished). For more information on the $\Sigma^0_k$ bounding principle, etc., see Kirby/Paris [141] and Hájek/Pudlák [100].

## II.4. The Number Systems

In this section we begin the development of ordinary mathematics within $\mathsf{RCA}_0$. We present what amounts to the usual Dedekind/Cauchy construction of the number systems.

We begin with the ring of integers $\mathbb{Z}$. The most basic properties of the natural number system $\mathbb{N}$ have already been developed (lemma II.2.1). We shall now define integers to be certain ordered pairs $(m, n) \in \mathbb{N} \times \mathbb{N}$. In order to do so, we first define the following operations and relations on $\mathbb{N} \times \mathbb{N}$:

$$\begin{aligned}
(m,n) +_{\mathbb{Z}} (p,q) &= (m+p, n+q),\\
(m,n) -_{\mathbb{Z}} (p,q) &= (m+q, n+p),\\
(m,n) \cdot_{\mathbb{Z}} (p,q) &= (m \cdot p + n \cdot q, m \cdot q + n \cdot p),\\
(m,n) <_{\mathbb{Z}} (p,q) &\leftrightarrow m + q < n + p,\\
(m,n) =_{\mathbb{Z}} (p,q) &\leftrightarrow m + q = n + p.
\end{aligned}$$

Clearly $=_{\mathbb{Z}}$ is an equivalence relation on $\mathbb{N} \times \mathbb{N}$. We define an *integer* to be any element of $\mathbb{N} \times \mathbb{N} \subseteq \mathbb{N}$ which is the least element of its equivalence class. (Here "least" refers to the ordering of $\mathbb{N}$.) We can prove in $\mathsf{RCA}_0$ that the set $\mathbb{Z}$ of all integers exists. We can then define $+, -, \cdot, 0, 1, <$ on $\mathbb{Z}$ accordingly. (For instance, for all $a, b \in \mathbb{Z}$, we define $a + b =$ the unique $c \in \mathbb{Z}$ such that $c =_{\mathbb{Z}} a +_{\mathbb{Z}} b$.) We can then prove:

Theorem II.4.1. *The following is provable in* $\mathsf{RCA}_0$. *The system*

$$\mathbb{Z}, +, -, \cdot, 0, 1, <$$

*is an ordered integral domain, is Euclidean, etc.*

Proof. We identify $m \in \mathbb{N}$ with $(m, 0) \in \mathbb{Z}$. Note that, under this identification, $(m, n) =_{\mathbb{Z}} m - n$. The proof of the basic properties of the ring of integers $\mathbb{Z}$ is straightforward using lemma II.2.1. □

Next we introduce the field $\mathbb{Q}$ of rational numbers. Let $\mathbb{Z}^+$ be the set of positive integers. Rational numbers will be defined to be certain ordered pairs $(a, b) \in \mathbb{Z} \times \mathbb{Z}^+$. We define the following operations and relations on $\mathbb{Z} \times \mathbb{Z}^+$:

$$\begin{aligned}(a,b) +_{\mathbb{Q}} (c,d) &= (a \cdot d + b \cdot c, b \cdot d),\\ (a,b) -_{\mathbb{Q}} (c,d) &= (a \cdot d - b \cdot c, b \cdot d),\\ (a,b) \cdot_{\mathbb{Q}} (c,d) &= (a \cdot c, b \cdot d),\\ (a,b) <_{\mathbb{Q}} (c,d) &\leftrightarrow a \cdot d < b \cdot c,\\ (a,b) =_{\mathbb{Q}} (c,d) &\leftrightarrow a \cdot d = b \cdot c.\end{aligned}$$

Again $=_{\mathbb{Q}}$ is an equivalence relation on $\mathbb{Z} \times \mathbb{Z}^+$, and we define a *rational number* to be any element of $\mathbb{Z} \times \mathbb{Z}^+ \subseteq \mathbb{N}$ which is the least element of its equivalence class. (Here "least" refers to the ordering of $\mathbb{N}$.) The set of all rational numbers is denoted $\mathbb{Q}$ and we define $+, -, \cdot, 0, 1, <$ on $\mathbb{Q}$ accordingly. We then prove:

THEOREM II.4.2. *The following is provable in* $\mathsf{RCA}_0$. *The system*

$$\mathbb{Q}, +, -, \cdot, 0, 1, <$$

*is an ordered field.*

PROOF. For all $r, s \in \mathbb{Q}$ with $s \neq 0$, we define $r/s =$ the unique $q \in \mathbb{Q}$ such that $q \cdot s = r$. We identify $a \in \mathbb{Z}$ with the unique $r \in \mathbb{Q}$ such that $r =_{\mathbb{Q}} (a, 1)$. Under this identification, for all $(a, b) \in \mathbb{Z} \times \mathbb{Z}^+$, $(a, b) = a/b$. The proof of theorem II.4.2 is straightforward using theorem II.4.1. □

We now introduce the real number system. We use a modification of the usual definition via Cauchy sequences of rational numbers.

DEFINITION II.4.3. A *sequence of rational numbers* is defined in $\mathsf{RCA}_0$ to be a function $f : \mathbb{N} \to \mathbb{Q}$. We usually denote such a sequence as $\langle q_k : k \in \mathbb{N} \rangle$ where $q_k = f(k)$.

DEFINITION II.4.4 (the real number system). A *real number* is defined in $\mathsf{RCA}_0$ to be a sequence of rational numbers $\langle q_k : k \in \mathbb{N} \rangle$ such that $\forall k \, \forall i$ $(|q_k - q_{k+i}| \leq 2^{-k})$. Here $|q|$ denotes the *absolute value* of a rational number $q \in \mathbb{Q}$, i.e., $|q| = q$ if $q \geq 0$, $-q$ otherwise. Two real numbers $\langle q_k : k \in \mathbb{N} \rangle$ and $\langle q'_k : k \in \mathbb{N} \rangle$ are said to be *equal* if $\forall k \, (|q_k - q'_k| \leq 2^{-k+1})$.

We shall often use special variables such as $x, y, \ldots$ to range over real numbers. We then write $x = y$ to mean that the real numbers $x$ and $y$ are equal in the sense of definition II.4.4. When describing definitions or proofs within $\mathsf{RCA}_0$, we shall sometimes use the symbol $\mathbb{R}$ informally to denote the set of all real numbers. Thus for instance $\forall x \in \mathbb{R} \ldots$ means $\forall x$ (if $x$ is a real number then $\ldots$). Of course the set $\mathbb{R}$ does not formally exist within $\mathsf{RCA}_0$, since $\mathsf{RCA}_0$ is limited to the language $\mathrm{L}_2$ of second order arithmetic.

Remark. Note that we are taking equality between real numbers (the $=$ of definition II.4.4) to be an equivalence relation rather than true identity. This choice is dictated by our goal of developing mathematics within subsystems of second order arithmetic such as $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$. One might consider alternative definitions under which a real number would be an equivalence class or a representative of an equivalence class. Both alternatives turn out to be inappropriate. Equivalence classes would require the language of third order arithmetic, and the use of representatives would demand a strong form of the axiom of choice which is not available even in full second order arithmetic, $\mathsf{Z}_2$.

Working within $\mathsf{RCA}_0$ we embed $\mathbb{Q}$ into $\mathbb{R}$ by identifying $q \in \mathbb{Q}$ with the real number $x_q = \langle q \rangle = \langle q_k : k \in \mathbb{N} \rangle$ where $q_k = q$ for all $k \in \mathbb{N}$. A real number $x$ is said to be *rational* if $x = x_q$ for some $q \in \mathbb{Q}$. (Here $=$ is as in definition II.4.4.)

The sum of two real numbers $x = \langle q_k : k \in \mathbb{N} \rangle$ and $y = \langle q'_k : k \in \mathbb{N} \rangle$ is defined by

$$x + y = \langle q_{k+1} + q'_{k+1} : k \in \mathbb{N} \rangle.$$

We note that $|(q_{k+1} + q'_{k+1}) - (q_{k+i+1} + q'_{k+i+1})| \leq |q_{k+1} - q_{k+i+1}| + |q'_{k+1} - q'_{k+i+1}| \leq 2^{-k-1} + 2^{-k-1} = 2^{-k}$ so $x + y$ is a real number. Trivially $-x = \langle -q_k : k \in \mathbb{N} \rangle$ is also a real number. We define $x \leq y$ if and only if $\forall k \, (q_k \leq q'_k + 2^{-k+1})$. Clearly $x = y$ if and only if $x \leq y$ and $y \leq x$. We define $x < y$ if and only if $y \not\leq x$. It is straightforward to verify in $\mathsf{RCA}_0$ that the system $\mathbb{R}, +, -, 0, 1, <$ obeys all the axioms for an ordered Abelian group, for example

$$x < y \vee x = y \vee x > y,$$
$$x < y \leftrightarrow x + z < y + z,$$

etc.

Note that formulas such as $x \leq y$, $x = y$, $x + y = z, \ldots$ are $\Pi^0_1$ while $x < y$, $x \neq 0, \ldots$ are $\Sigma^0_1$.

Multiplication of real numbers $x = \langle q_k : k \in \mathbb{N} \rangle$ and $y = \langle q'_k : k \in \mathbb{N} \rangle$ is defined by

$$x \cdot y = \langle q_{n+k} \cdot q'_{n+k} : k \in \mathbb{N} \rangle$$

where $n$ is as small as possible such that $2^n \geq |q_0| + |q'_0| + 2$. We note that $x \cdot y$ is a real number since

$$\begin{aligned} |q_{n+k} \cdot q'_{n+k} - q_{n+k+i} \cdot q'_{n+k+i}| & \\ &\leq |q_{n+k}| \cdot |q'_{n+k} - q'_{n+k+i}| + |q_{n+k} - q_{n+k+i}| \cdot |q'_{n+k+i}| \\ &\leq 2^{-n-k} \, (|q_0| + |q'_0| + 2) \\ &\leq 2^{-k}. \end{aligned}$$

We can then prove straightforwardly:

THEOREM II.4.5. *It is provable in* $\mathsf{RCA}_0$ *that the real number system*

$$\mathbb{R}, +, -, \cdot, 0, 1, <, =$$

*obeys all the axioms of an Archimedean ordered field.*

It is natural now to ask whether the real number system is complete. In $\mathsf{RCA}_0$ we cannot discuss arbitrary bounded subsets of $\mathbb{R}$. Thus we cannot even formulate the least upper bound principle in full generality. However, we can discuss sequences of elements of $\mathbb{R}$.

DEFINITION II.4.6 (sequences of real numbers). Within $\mathsf{RCA}_0$, a *sequence of real numbers* is a function $f : \mathbb{N} \times \mathbb{N} \to \mathbb{Q}$ such that for each $n \in \mathbb{N}$ the function $(f)_n : \mathbb{N} \to \mathbb{Q}$ defined by $(f)_n(k) = f((k, n))$ is a real number (in the sense of definition II.4.4). We shall employ notations such as $\langle x_n : n \in \mathbb{N} \rangle$ for the sequence $f$ with $(f)_n = x_n$.

Using the previous definition we can discuss sequential convergence within $\mathsf{RCA}_0$. We say that the sequence $\langle x_n : n \in \mathbb{N} \rangle$ *converges* to $x$, written $x = \lim_n x_n$, if $\forall \epsilon > 0 \, \exists n \, \forall i \, (|x - x_{n+i}| < \epsilon)$. The sequence $\langle x_n : n \in \mathbb{N} \rangle$ is said to be *convergent* if $\lim_n x_n$ exists.

Unfortunately, the axioms of $\mathsf{RCA}_0$ are not even strong enough to prove that $\mathbb{R}$ is sequentially complete. This is shown by the following counterexample.

EXAMPLE II.4.7. Let $f : \omega \to \omega$ be a one-to-one recursive function whose range is not recursive. For each $n \in \omega$ put

$$c_n = \sum_{i=0}^{n} 2^{-f(i)}.$$

Clearly $c_0 < c_1 < \cdots < c_n < \cdots < 2$ so $\langle c_n : n \in \omega \rangle$ is a recursive, bounded, increasing sequence of rational numbers. However, the real number $c = \lim_n c_n$ is clearly not recursive.

From the above counterexample, it follows that the least upper bound principle for sequences of real numbers is false in the $\omega$-model $\mathrm{REC} = \{X \subseteq \omega : X \text{ is recursive}\}$. Since $\mathrm{REC} \models \mathsf{RCA}_0$, it follows that the least upper bound principle for sequences of real numbers is not provable in $\mathsf{RCA}_0$.

However, not all is lost. The following *nested interval completeness* property of $\mathbb{R}$ is provable in $\mathsf{RCA}_0$ and suffices for many purposes.

THEOREM II.4.8 (nested interval completeness). *The following is provable in* $\mathsf{RCA}_0$. *Let* $\langle a_n : n \in \mathbb{N} \rangle$ *and* $\langle b_n : n \in \mathbb{N} \rangle$ *be sequences of real numbers such that for all* $n$, $a_n \leq a_{n+1} \leq b_{n+1} \leq b_n$, *and* $\lim_n |a_n - b_n| = 0$. *Then there exists a real number* $x$ *such that* $x = \lim_n a_n = \lim_n b_n$.

PROOF. Let $\langle q_{nk} : n, k \in \mathbb{N} \rangle$ and $\langle q'_{nk} : n, k \in \mathbb{N} \rangle$ be double sequences of rationals such that for all $n$, $a_n = \langle q_{nk} : k \in \mathbb{N} \rangle$ and $b_n = \langle q'_{nk} : k \in \mathbb{N} \rangle$. (Compare definitions II.4.3, II.4.4, and II.4.6.) Clearly for each $k$ there

exists $n$ such that $n \geq k+2$ and $|q_{nn} - q'_{nn}| \leq 2^{-k-2}$. Let $f(k)$ be the least such $n$ (theorem II.3.5) and put $x = \langle q''_k : k \in \mathbb{N} \rangle$ where $q''_k = q_{f(k),f(k)}$. It is straightforward to verify that $x$ is a real number and that $a_n \leq x \leq b_n$ for all $n$. Thus $x = \lim_n a_n = \lim_n b_n$. This completes the proof. □

Using nested interval completeness, we can prove that $\mathbb{R}$ is uncountable:

THEOREM II.4.9 (uncountability of $\mathbb{R}$). *The following is provable in* $\mathsf{RCA}_0$. *For any sequence of real numbers* $\langle x_n : n \in \mathbb{N} \rangle$ *there exists a real number* $y$ *such that* $\forall n\,(x_n \neq y)$.

PROOF. Let $\langle q_{nk} : n \in \mathbb{N}, k \in \mathbb{N} \rangle$ be a double sequence of rational numbers such that $x_n = \langle q_{nk} : k \in \mathbb{N} \rangle$ for each $n$. By primitive recursion (theorem II.3.4) define a sequence of rational intervals $\langle (a_n, b_n) : n \in \mathbb{N} \rangle$ as follows: $(a_0, b_0) = (0, 1)$;

$$(a_{n+1}, b_{n+1}) = \begin{cases} ((a_n + 3b_n)/4, b_n) & \text{if } q_{n,2n+3} \leq (a_n + b_n)/2, \\ (a_n, (3a_n + b_n)/4) & \text{otherwise.} \end{cases}$$

For each $n$ we have $|a_n - b_n| = 2^{-2n}$ so $\lim_n |a_n - b_n| = 0$. By theorem II.4.8 let $y = \lim_n a_n = \lim_n b_n$. (Alternatively we could just define $y$ to be the rational sequence $\langle a_n : n \in \mathbb{N} \rangle$ and note directly that $y$ is a real number.) If $q_{n,2n+3} \leq \frac{1}{2}(a_n + b_n)$, we have $x_n \leq \frac{1}{2}(a_n + b_n) + 2^{-2n-3} < a_{n+1} \leq y$. In the other case we have $x_n \geq \frac{1}{2}(a_n + b_n) - 2^{-2n-3} > b_{n+1} \geq y$. Thus $\forall n\,(x_n \neq y)$. □

In a similar vein we can prove the *Baire category theorem* for $\mathbb{R}^k$, $k \in \mathbb{N}$, within $\mathsf{RCA}_0$. First we present the relevant definitions. Within $\mathsf{RCA}_0$ we define a *point of* $\mathbb{R}^k$ to be a finite sequence of real numbers of length $k$. We use notations such as $\langle x_1, \ldots, x_k \rangle$ for points of $\mathbb{R}^k$. Within $\mathsf{RCA}_0$ we define a (code for a) *basic open set* in $\mathbb{R}^k$ to be an ordered $2k$-tuple of rational numbers $\langle a_1, b_1, \ldots, a_k, b_k \rangle \in \mathbb{Q}^{2k}$ such that $a_i < b_i$ for all $i$, $1 \leq i \leq k$. A (code for an) *open set* in $\mathbb{R}^k$ is any set $U$ of (codes for) basic open sets in $\mathbb{R}^k$. We then define $\langle x_1, \ldots, x_k \rangle \in U$ to mean that there exists $\langle a_1, b_1, \ldots, a_k, b_k \rangle \in U$ such that $a_i < x_i < b_i$ for all $i$, $1 \leq i \leq k$. An open set $U$ in $\mathbb{R}^k$ is said to be *dense* if it contains points from each basic open set in $\mathbb{R}^k$. Using these definitions we have the Baire category theorem for $\mathbb{R}^k$:

THEOREM II.4.10 (Baire category theorem for $\mathbb{R}^k$). *The following is provable in* $\mathsf{RCA}_0$. *Let* $\langle U_n : n \in \mathbb{N} \rangle$ *be a sequence of dense open sets in* $\mathbb{R}^k$. *Then there exists* $x \in \mathbb{R}^k$ *such that* $x \in U_n$ *for all* $n \in \mathbb{N}$.

PROOF. Similar to the proof of the previous theorem. □

In the next section, theorems II.4.8, II.4.9 and II.4.10 as well as the definitions preceding theorem II.4.10 will be generalized to the context of complete separable metric spaces.

Exercise II.4.11 (real linear algebra). Show that $\mathsf{RCA}_0$ is strong enough to develop the basics of real linear algebra, including Gaussian elimination, etc.

Hint: Given a generic system of linear equations

$$\begin{aligned} a_{11}x_1 + \cdots + a_{1n}x_n &= b_1 \\ &\vdots \\ a_{m1}x_1 + \cdots + a_{mn}x_n &= b_m \end{aligned}$$

we can form a finite decision tree $T_{mn}$ representing all of the possibilities for Gaussian elimination. Each node $v \in T_{mn}$ has at most two immediate successors which are distinguished by whether a certain integer polynomial $p_v$ in the coefficients

$$a_{11}, \ldots, a_{1n}, \ldots, a_{m1}, \ldots, a_{mn} \tag{4}$$

is equal or unequal to 0. By bounded $\Sigma^0_1$ comprehension in $\mathsf{RCA}_0$, any particular set of real coefficients (4) gives rise to a path through $T_{mn}$ describing this instance of Gaussian elimination.

**Notes for §II.4.** Our treatment of the real number system in the context of $\mathsf{RCA}_0$ is analogous to that of Aberth [2] in the somewhat different context of recursive analysis. For a constructivist treatment, see Bishop/Bridges [20]. In an early paper Simpson [236] developing mathematics within $\mathsf{RCA}_0$, we defined a real number to be the set of smaller rational numbers. This alternative definition, although in a sense equivalent to definition II.4.4 above, turns out to be inappropriate for other reasons, as explained in Brown/Simpson [27, §3].

## II.5. Complete Separable Metric Spaces

In the previous section we defined the real numbers, within $\mathsf{RCA}_0$, to be the "completion" of the rational numbers. We shall now use the same idea to define a complete separable metric space $\widehat{A}$, within $\mathsf{RCA}_0$, to be the "completion" of its countable dense subset $A$.

Definition II.5.1 (complete separable metric spaces). A (code for a) *complete separable metric space* $\widehat{A}$ is defined in $\mathsf{RCA}_0$ to be a nonempty set $A \subseteq \mathbb{N}$ together with a sequence of real numbers $d : A \times A \to \mathbb{R}$ such that $d(a,a) = 0$, $d(a,b) = d(b,a) \geq 0$, and $d(a,b) + d(b,c) \geq d(a,c)$ for all $a, b, c \in A$. A *point* of $\widehat{A}$ is a sequence $x = \langle a_k : k \in \mathbb{N} \rangle$ of elements of $A$, such that $\forall i \, \forall j \, (i < j \to d(a_i, a_j) \leq 2^{-i})$. We write $x \in \widehat{A}$ to mean that $x$ is a point of $\widehat{A}$.

If $x = \langle a_k : k \in \mathbb{N} \rangle$ and $y = \langle b_k : k \in \mathbb{N} \rangle$ are points of $\widehat{A}$, we define $d(x, y) = \lim_k d(a_k, b_k)$. We define $x = y$ to mean that $d(x, y) = 0$. Note that the condition $x = y$ is $\Pi^0_1$ since it is equivalent to $\forall k \, (d(a_k, b_k) \leq 2^{-k+1})$.

Each $a \in A$ is identified with the point $x_a = \langle a : k \in \mathbb{N} \rangle \in \widehat{A}$. Thus by definition the countable set $A$ is dense in $\widehat{A}$; indeed, for all $x \in \widehat{A}$ we have $d(x, a_k) \leq 2^{-k}$, where $x = \langle a_k : k \in \mathbb{N} \rangle$. This justifies our designation of $\widehat{A}$ as "separable." In order to justify our designation of $\widehat{A}$ as "complete," we present the following exercise generalizing our earlier discussion of nested interval completeness.

Exercise II.5.2. Within $\mathsf{RCA}_0$, show that $\widehat{A}$ is complete in the following sense. Let $\langle x_n : n \in \mathbb{N} \rangle$ be a sequence of points of $\widehat{A}$. Assume that there exists a sequence of real numbers $\langle r_n : n \in \mathbb{N} \rangle$ such that $\forall m \, \forall n \, (m < n \to d(x_n, x_m) \leq r_m)$ and $\lim_n r_n = 0$. Then $\langle x_n : n \in \mathbb{N} \rangle$ is *convergent*, i.e., there exists a point $x \in \widehat{A}$ (unique up to $=$ as defined in II.5.1) such that $x = \lim_n x_n$.

We now give some examples and constructions of complete separable metric spaces, within $\mathsf{RCA}_0$.

Example II.5.3 (the real numbers). Within $\mathsf{RCA}_0$, for $q, q' \in \mathbb{Q}$ define $d(q, q') = |q - q'|$. Then $\widehat{\mathbb{Q}} = \mathbb{R}$, i.e., the reals are the completion of the rationals. More generally, any closed (bounded or unbounded) interval of $\mathbb{R}$ is a complete separable metric space with the same metric. For example we have the *closed unit interval*

$$[0, 1] = \{x : 0 \leq x \leq 1\}.$$

Example II.5.4 (finite product spaces). Within $\mathsf{RCA}_0$ we can define the notion of a sequence of codes for complete separable metric spaces. Given a finite sequence of such codes $A_i, 1 \leq i \leq m$, we can form the $m$-fold Cartesian product

$$A = A_1 \times \cdots \times A_m = \{\langle a_1, \ldots, a_m \rangle : a_i \in A_i\}$$

and define $d : A \times A \to \mathbb{R}$ by

$$d(\langle a_1, \ldots, a_m \rangle, \langle b_1, \ldots, b_m \rangle) = \sqrt{d_1(a_1, b_1)^2 + \cdots + d_m(a_m, b_m)^2}.$$

We can then prove within $\mathsf{RCA}_0$ the following facts: (i) $\widehat{A}$ is a complete separable metric space; (ii) the points of $\widehat{A}$ can be identified with finite sequences $\langle x_1, \ldots, x_m \rangle$ with $x_i \in \widehat{A}_i$ for $1 \leq i \leq m$; and (iii) under this identification, the metric on $\widehat{A}$ is given by

$$d(\langle x_1, \ldots, x_m \rangle, \langle y_1, \ldots, y_m \rangle) = \sqrt{d_1(x_1, y_1)^2 + \cdots + d_m(x_m, y_m)^2}.$$

Thus we are justified in writing

$$\widehat{A} = \widehat{A}_1 \times \cdots \times \widehat{A}_m = \prod_{i=1}^{m} \widehat{A}_i.$$

In particular we have within $\mathsf{RCA}_0$ the $m$-dimensional Euclidean spaces $\mathbb{R}^m$ for all $m \in \mathbb{N}$. The points of $\mathbb{R}^m$ can be identified with $m$-tuples $\langle x_1, \ldots, x_m \rangle$, $x_i \in \mathbb{R}$.

EXAMPLE II.5.5 (infinite product spaces). Given an infinite sequence of (codes for) complete separable metric spaces $\widehat{A}_i$, $i \in \mathbb{N}$, we can form the infinite product space $\widehat{A} = \prod_{i=0}^{\infty} \widehat{A}_i$ as follows. For each $i \in \mathbb{N}$, we let $c_i$ be the smallest element of $A_i \subseteq \mathbb{N}$ (in the usual ordering of $\mathbb{N}$). We define

$$A = \bigcup_{m=0}^{\infty} (A_0 \times \cdots \times A_m) = \{\langle a_i : i \leq m \rangle : m \in \mathbb{N}, a_i \in A_i\}$$

and $d : A \times A \to \mathbb{R}$ by

$$d(\langle a_i : i \leq m \rangle, \langle b_i : i \leq n \rangle) = \sum_{i=0}^{\infty} \frac{d_i(a_i', b_i')}{1 + d_i(a_i', b_i')} \cdot \frac{1}{2^i}$$

where

$$a_i' = \begin{cases} a_i & \text{if } i \leq m, \\ c_i & \text{otherwise} \end{cases}$$

and

$$b_i' = \begin{cases} b_i & \text{if } i \leq m, \\ c_i & \text{otherwise.} \end{cases}$$

We can then prove within $\mathsf{RCA}_0$ the following facts: (i) $\widehat{A}$ is a complete separable metric space; (ii) the points of $\widehat{A}$ can be identified with the sequences $\langle x_i : i \in \mathbb{N} \rangle$ where $x_i \in \widehat{A}_i$ for all $i \in \mathbb{N}$; and (iii) under this identification, the metric on $\widehat{A}$ is given by

$$d(\langle x_i : i \in \mathbb{N} \rangle, \langle y_i : i \in \mathbb{N} \rangle) = \sum_{i=0}^{\infty} \frac{d_i(x_i, y_i)}{1 + d_i(x_i, y_i)} \cdot \frac{1}{2^i}.$$

These three conditions define the usual textbook construction of the product of a sequence of complete separable metric spaces. Thus we are justified in writing

$$\widehat{A} = \prod_{i=0}^{\infty} \widehat{A}_i.$$

In particular, we have within $\mathsf{RCA}_0$ the *Cantor space*

$$2^{\mathbb{N}} = \{0,1\}^{\mathbb{N}} = \prod_{i=0}^{\infty} \{0,1\},$$

the *Baire space*

$$\mathbb{N}^{\mathbb{N}} = \prod_{i=0}^{\infty} \mathbb{N},$$

and the *Hilbert cube*

$$[0,1]^{\mathbb{N}} = \prod_{i=0}^{\infty} [0,1].$$

The points of the Cantor space and the Baire space can be identified with functions $f : \mathbb{N} \to \{0,1\}$ and $f : \mathbb{N} \to \mathbb{N}$ respectively. The points of the Hilbert cube can be identified with sequences $\langle x_i : i \in \mathbb{N} \rangle$, $0 \leq x_i \leq 1$.

We now begin our discussion of the topology of complete separable metric spaces. This discussion will be continued in §§II.6, II.7 and II.10 and in chapters II–VI.

Definition II.5.6 (open sets). Within $\mathsf{RCA}_0$, let $\widehat{A}$ be a complete separable metric space. A (code for an) *open set* $U$ in $\widehat{A}$ is a set $U \subseteq \mathbb{N} \times A \times \mathbb{Q}^+$, where

$$\mathbb{Q}^+ = \{q \in \mathbb{Q} : q > 0\}.$$

A point $x \in \widehat{A}$ is said to *belong to* $U$ (abbreviated $x \in U$) if

$$\exists n \, \exists a \, \exists r \, ((d(x,a) < r \wedge (n,a,r) \in U).$$

Note that the formula $x \in U$ is $\Sigma^0_1$.

We regard $(a,r) \in A \times \mathbb{Q}^+$ as a code for the basic open ball $\mathrm{B}(a,r)$ consisting of all points $x \in \widehat{A}$ such that $d(x,a) < r$. The idea of the preceding definition is that $U$ encodes the open set which is the union of the balls $\mathrm{B}(a,r)$ such that $\exists n \, ((n,a,r) \in U)$. We shall sometimes use notations such as $(a,r) < U$ meaning that

$$\exists n \, \exists b \, \exists s \, (d(a,b) + r < s \wedge (n,b,s) \in U).$$

Note that this condition is $\Sigma^0_1$ and implies that the closure of $\mathrm{B}(a,r)$ is included in $U$. We write $(a,r) < (b,s)$ to mean $d(a,b) + r < s$.

The following lemma will provide many examples of open sets within $\mathsf{RCA}_0$.

Lemma II.5.7. *For any $\Sigma^0_1$ formula $\varphi(x)$, the following is provable in $\mathsf{RCA}_0$. Let $\widehat{A}$ be a complete separable metric space. Assume that for all $x$ and $y \in \widehat{A}$, $x = y$ and $\varphi(x)$ imply $\varphi(y)$. Then there exists an open set $U \subseteq \widehat{A}$ such that for all $x \in \widehat{A}$, $x \in U$ if and only if $\varphi(x)$.*

PROOF. By the normal form theorem for $\Sigma^0_1$ formulas (theorem II.2.7), there exists a $\Sigma^0_0$ formula $\theta(n)$ such that $\mathsf{RCA}_0$ proves: for all $x = \langle a_k : k \in \mathbb{N}\rangle \in \widehat{A}$, $\varphi(x) \leftrightarrow \exists m\, \theta(\langle a_k : k \leq m\rangle)$. We reason within $\mathsf{RCA}_0$. By $\Sigma^0_0$ comprehension, let $U$ be the set of all $(n, a, r) \in \mathbb{N} \times A \times \mathbb{Q}^+$ such that, for some $m \in \mathbb{N}$, $n = \langle a_k : k \leq m\rangle \in A^{m+1}$ and $\theta(\langle a_k : k \leq m\rangle)$ holds and $a = a_m$ and $r = 2^{-m-1}$ and

$$(\forall i \leq m)\,(\forall j \leq m)\,(i < j \to d(a_i, a_j)_{m+1} \leq 2^{-i-1}).$$

(Here $d(a,b)_k$ denotes the kth rational approximation to the real number $d(a,b)$, i.e., $d(a,b)_k = q_k \in \mathbb{Q}$ where $d(a,b) = \langle q_k : k \in \mathbb{N}\rangle \in \mathbb{R}$.)

Thus $U$ is (a code for) an open set in $\widehat{A}$. It remains to prove that, for all $y \in \widehat{A}$, $y \in U$ if and only if $\varphi(y)$.

Assume first that $y \in U$. Then $d(a, y) < r$ for some $(n, a, r) \in U$. Let $n = \langle a_k : k \leq m\rangle$ as above. Thus $a = a_m$, $r = 2^{-m-1}$, and $d(a_m, y) < 2^{-m-1}$. Write $y = \langle b_k : k \in \mathbb{N}\rangle$ and let $m' > m$ be so large that $d(a_m, b_j) \leq 2^{-m-1}$ for all $j \geq m'$. Then for all $i < m$ and $j \geq m'$ we have

$$\begin{aligned} d(a_i, b_j) &\leq d(a_i, a_m) + d(a_m, b_j) \\ &\leq d(a_i, a_m)_{m+1} + 2^{-m-1} + d(a_m, b_j) \\ &\leq 2^{-i-1} + 2^{-m-1} + 2^{-m-1} \\ &\leq 2^{-i}. \end{aligned}$$

Put $z = \langle a_0, a_1, \ldots, a_m\rangle^\frown\langle b_{m'}, b_{m'+1}, \ldots\rangle$. Then by the previous inequality we have $z \in \widehat{A}$. Moreover $z = y$, and $\varphi(z)$ holds. Hence $\varphi(y)$ holds.

Conversely, assume that $\varphi(y)$ holds. Write $y = \langle b_k : k \in \mathbb{N}\rangle$. Put $x = \langle a_k : k \in \mathbb{N}\rangle$ where $a_k = b_{k+2}$ for all $k \in \mathbb{N}$. Then $x \in \widehat{A}$, and $x = y$, so $\varphi(x)$ holds. Moreover, for all $i < j \in \mathbb{N}$ we have $d(a_i, a_j) = d(b_{i+2}, b_{j+2}) \leq 2^{-i-2}$, hence $d(a_i, a_j)_k \leq 2^{-i-2} + 2^{-k} \leq 2^{-i-1}$ for all $k \geq i+2$. Let $m$ be such that $\theta(\langle a_k : k \leq m\rangle)$ holds. Put $n = \langle a_k : k \leq m\rangle$, $a = a_m$, and $r = 2^{-m-1}$. Then $(n, a, r) \in U$. Also $d(a, y) = d(a_m, x) = \lim_j d(a_m, a_j) \leq 2^{-m-2} < 2^{-m-1} = r$, which implies that $y \in U$.

This completes the proof. □

We shall now prove the following $\mathsf{RCA}_0$ version of the *Baire category theorem*.

THEOREM II.5.8 (Baire category theorem). *The following is provable in* $\mathsf{RCA}_0$. *Let* $\langle U_k : k \in \mathbb{N}\rangle$ *be a sequence of dense open sets in* $\widehat{A}$. *Then* $\bigcap_{k\in\mathbb{N}} U_k$ *is dense in* $\widehat{A}$.

PROOF. We reason within $\mathsf{RCA}_0$. We wish to show that $\bigcap_{k\in\mathbb{N}} U_k$ is dense in $\widehat{A}$. Given $y \in \widehat{A}$ and $\epsilon > 0$, we must find $x \in \widehat{A}$ such that $d(x, y) < \epsilon$ and $x \in U_k$ for all $k \in \mathbb{N}$. We shall define the point $x = \langle a_k : k \in \mathbb{N}\rangle$

by recursion on $k$. Since $U_0$ is dense, we can find $(a_0, r_0) \in A \times \mathbb{Q}^+$ such that $(a_0, r_0) < (y, \epsilon)$, $(a_0, r_0) < U_0$, and $r_0 \leq 1/2$. Let $\varphi(k, a, r, b, s)$ be a $\Sigma^0_1$ formula which expresses the following: $(a, r) \in A \times \mathbb{Q}^+$, $(b, s) \in A \times \mathbb{Q}^+$, $(b, s) < (a, r)$, $(b, s) < U_k$, and $s \leq 2^{-k-1}$. From the density of $U_k$, it follows that for each $(k, a, r) \in \mathbb{N} \times A \times \mathbb{Q}^+$ there exists $(b, s)$ such that $\varphi(k, a, r, b, s)$. Write

$$\varphi(k, a, r, b, s) \equiv \exists n\, \theta(k, a, r, b, s, n)$$

where $\theta$ is $\Sigma^0_0$. By minimization (theorem II.3.5), there exists a function

$$f : \mathbb{N} \times A \times \mathbb{Q}^+ \to \mathbb{N} \times A \times \mathbb{Q}^+$$

such that $f(k, a, r)$ is the least $(n, b, s)$ such that $\theta(k, a, r, b, s, n)$ holds. By primitive recursion (theorem II.3.4), there exists a function $g : \mathbb{N} \to A \times \mathbb{Q}^+$ such that $g(0) = (a_0, r_0)$ and, for all $k \in \mathbb{N}$, $g(k+1) = (a_{k+1}, r_{k+1})$ where $f(k, a_k, r_k) = (n_k, a_{k+1}, r_{k+1})$. Hence $\varphi(k, a_k, r_k, a_{k+1}, r_{k+1})$ holds for all $k$. It is not hard to check that $x = \langle a_k : k \in \mathbb{N} \rangle$ is a point of $\widehat{A}$ and that $x \in U_k$ for all $k$, and $d(x, y) < \epsilon$. This completes the proof. □

Corollary II.5.9. *The following is provable in* $\mathsf{RCA}_0$. *Let $\widehat{A}$ be a complete separable metric space with no isolated points. Then $\widehat{A}$ is uncountable, i.e., for all sequences of points $\langle x_k : k \in \mathbb{N} \rangle$, $x_k \in \widehat{A}$, there exists a point $y \in \widehat{A}$ such that $\forall k\, (x_k \neq y)$.*

Proof. We reason within $\mathsf{RCA}_0$. Let $\varphi(k, y)$ be a $\Sigma^0_1$ formula (with parameter $\langle x_k : k \in \mathbb{N} \rangle$) which says that $y \neq x_k$. By lemma II.5.7, $\mathsf{RCA}_0$ proves the existence of a sequence of open sets $\langle U_k : k \in \mathbb{N} \rangle$ such that, for all $y \in \widehat{A}$ and $k \in \mathbb{N}$, $y \in U_k$ if and only if $\varphi(k, y)$. For each $k \in \mathbb{N}$, since $x_k$ is not an isolated point, $U_k$ is dense. The desired conclusion follows from the Baire category theorem II.5.8. □

Exercise II.5.10. In $\mathsf{RCA}_0$ show that, given a sequence $\langle U_n : n \in \mathbb{N} \rangle$ of (codes for) open sets in $\widehat{A}$, we can effectively find (a code for) an open set $U$ in $\widehat{A}$ such that for all points $x \in \widehat{A}$, $x \in U$ if and only if $\exists n\, (x \in U_n)$. Thus we are justified in writing $U = \bigcup_{n \in \mathbb{N}} U_n$ and in saying that the union of countably many open sets is open.

Exercise II.5.11. In $\mathsf{RCA}_0$ show that, given a finite sequence $\langle U_k : k < n \rangle$ of (codes for) open sets in $\widehat{A}$, we can effectively find (a code for) an open set $U$ in $\widehat{A}$ such that, for all points $x \in \widehat{A}$, $x \in U$ if and only if $x \in U_k$ for all $k < n$. Thus we are justified in writing $U = \bigcap_{k=0}^{n-1} U_k$ and in saying that the intersection of finitely many open sets is open.

Definition II.5.12 (closed sets). Let $\widehat{A}$ be a complete separable metric space. A *closed set* in $\widehat{A}$ is defined in $\mathsf{RCA}_0$ to be the complement of an open set in $\widehat{A}$. In other words, we define a code for a closed set $C$ to be the same thing as a code for an open set $U$, and we define $x \in C$ if and only if $x \notin U$. Note that the formula $x \in C$ is $\Pi^0_1$.

Exercise II.5.13. Within $\mathsf{RCA}_0$ show that, in any complete separable metric space $\widehat{A}$, the countable intersection and finite union of closed sets is closed.

Exercise II.5.14. Within $\mathsf{RCA}_0$ show that the open unit interval

$$(0,1) = \{x : 0 < x < 1\}$$

is a complete separable metric space under

$$d(x,y) = |x - y| + \left| \frac{1}{h(x)} - \frac{1}{h(y)} \right|$$

where

$$h(x) = \frac{1}{2} - \left| \frac{1}{2} - x \right|.$$

Exercise II.5.15. Show that the following is provable in $\mathsf{RCA}_0$. If $\widehat{A}$ is a complete separable metric space and if $U$ is a nonempty open set in $\widehat{A}$, there exists a complete separable metric space $\widehat{B}$ which is *homeomorphic to* $U$, i.e., there exist continuous functions $f : \widehat{B} \to U$, $g : U \to \widehat{B}$ such that $f(g(x)) = x$ for all $x \in U$. (Continuous functions will be defined in the next section.)

Remark II.5.16. The previous exercise does not go through in $\mathsf{RCA}_0$ if we replace the nonempty open set $U$ by a nonempty closed set $C$. See exercise IV.2.11.

For more on complete separable metric spaces in $\mathsf{RCA}_0$, see §§II.6, II.7 and II.10. See also chapters III and IV.

**Notes for §II.5.** Our definition of complete separable metric space within $\mathsf{RCA}_0$ (II.5.1) comes from Brown/Simpson [27]. Lemma II.5.7 is due to Simpson, unpublished. Our $\mathsf{RCA}_0$ version of the Baire category theorem (II.5.8) is due to Simpson, unpublished. A stronger version of the Baire category theorem is discussed in Brown/Simpson [28]; see also Mytilinaios/Slaman [194]. Alternative notions of closed set are considered in Brown [25] and Giusto/Simpson [93].

## II.6. Continuous Functions

In this section we continue the work of the previous section. We show that certain portions of the theory of continuous functions on complete separable metric spaces can be developed within $\mathsf{RCA}_0$. For more information on complete separable metric spaces and continuous functions, see the next section.

DEFINITION II.6.1 (continuous functions). Within $\mathsf{RCA}_0$, let $\widehat{A}$ and $\widehat{B}$ be complete separable metric spaces. A (code for a) *continuous partial function* $\phi$ from $\widehat{A}$ to $\widehat{B}$ is a set of quintuples $\Phi \subseteq \mathbb{N} \times A \times \mathbb{Q}^+ \times B \times \mathbb{Q}^+$ which is required to have certain properties. We write $(a,r)\Phi(b,s)$ as an abbreviation for $\exists n\,((n,a,r,b,s) \in \Phi)$. The properties which we require are:

1. if $(a,r)\Phi(b,s)$ and $(a,r)\Phi(b',s')$, then $d(b,b') \leq s + s'$;
2. if $(a,r)\Phi(b,s)$ and $(a',r') < (a,r)$, then $(a',r')\Phi(b,s)$;
3. if $(a,r)\Phi(b,s)$ and $(b,s) < (b',s')$, then $(a,r)\Phi(b',s')$;

where the notation $(a',r') < (a,r)$ means that $d(a,a') + r' < r$.

The idea of the definition is that $\Phi$ encodes a partially defined, continuous function $\phi$ from $\widehat{A}$ to $\widehat{B}$. Recall from the previous section that $\mathrm{B}(a,r)$ denotes the basic open ball centered at $a$ with radius $r$. Intuitively, $(a,r)\Phi(b,s)$ is a piece of information to the effect that $\phi(x) \in$ the closure of $\mathrm{B}(b,s)$ whenever $x \in \mathrm{B}(a,r)$, provided $\phi(x)$ is defined. This is made precise in the following two paragraphs.

A point $x \in \widehat{A}$ is said to *belong to the domain of* $\phi$, abbreviated $x \in \mathrm{dom}(\phi)$, provided the code $\Phi$ of $\phi$ contains sufficient information to evaluate $\phi$ at $x$. This means that for all $\epsilon > 0$ there exists $(a,r)\Phi(b,s)$ such that $d(x,a) < r$ and $s < \epsilon$. If $x \in \mathrm{dom}(\phi)$, we define the value $\phi(x)$ to be the unique point $y \in \widehat{B}$ such that $d(y,b) \leq s$ for all $(a,r)\Phi(b,s)$ with $d(x,a) < r$. If $x \in \mathrm{dom}(\phi)$, we can use the code $\Phi$ and minimization (theorem II.3.5) to prove within $\mathsf{RCA}_0$ that $\phi(x)$ exists. Then, using condition II.6.1.1, it is easy to prove within $\mathsf{RCA}_0$ that $\phi(x)$ is unique (up to equality of points in $\widehat{B}$, as defined in II.5.1).

We write $\phi(x)$ *is defined* to mean that $x \in \mathrm{dom}(\phi)$. We say that $\phi$ is *totally defined on* $\widehat{A}$ if $\phi(x)$ is defined for all $x \in \widehat{A}$. We write $\phi\colon \widehat{A} \to \widehat{B}$ to mean that $\phi$ is a continuous, totally defined function from $\widehat{A}$ to $\widehat{B}$.

We now present some examples of (codes for) continuous functions within $\mathsf{RCA}_0$.

LEMMA II.6.2. *Within* $\mathsf{RCA}_0$, *let* $\widehat{A}$ *and* $\widehat{B}$ *be complete separable metric spaces.*

1. *The identity function* $\phi\colon \widehat{A} \to \widehat{A}$ *given by* $\phi(x) = x$ *is continuous.*
2. *For any* $y \in \widehat{B}$, *the constant function* $\phi\colon \widehat{A} \to \widehat{B}$, *given by* $\phi(x) = y$ *for all* $x \in \widehat{A}$, *is continuous.*
3. *The metric* $d\colon \widehat{A} \times \widehat{A} \to \mathbb{R}$ *is continuous.*

PROOF. For part 1, let $\varphi(a,r,b,s)$ be a $\Sigma^0_1$ formula which says that $(a,r),(b,s) \in A \times \mathbb{Q}^+$ and $(a,r) < (b,s)$. (Recall that $(a,r) < (b,s)$ is an abbreviation for $d(a,b) + r < s$.) Write $\varphi(a,r,b,s) \equiv \exists n\,\theta(n,a,r,b,s)$ where $\theta$ is $\Sigma^0_0$. By $\Sigma^0_0$ comprehension, let $\Phi$ be the set of $(n,a,r,b,s)$ such that $\theta(n,a,r,b,s)$ holds. It is straightforward to check that $\Phi$ is a code for a continuous function $\phi\colon \widehat{A} \to \widehat{A}$, and that $\phi(x) = x$ for all $x \in \widehat{A}$. (The

proof of part 1 should be studied carefully. The same idea will be used in all later constructions of continuous functions within $\mathsf{RCA}_0$.)

For part 2, let $\Phi$ be such that $(a,r)\Phi(b,s)$ if and only if $(a,r) \in A \times \mathbb{Q}^+$, $(b,s) \in B \times \mathbb{Q}^+$, and $d(b,y) < s$. It is straightforward to check that $\Phi$ is a code for a continuous function $\phi\colon \widehat{A} \to \widehat{B}$, and that $\phi(x) = y$ for all $x \in \widehat{A}$.

For part 3, let $\Phi$ be such that $(a,r)\Phi(b,s)$ if and only if $a = (a_1,a_2) \in A \times A$, $r \in \mathbb{Q}^+$, $b \in \mathbb{Q}$, $s \in \mathbb{Q}^+$, and $|d(a_1,a_2) - b| + 2r < s$. It is not difficult to check that $\Phi$ is a code for a continuous function $\phi\colon \widehat{A} \times \widehat{A} \to \mathbb{R}$, and that $\phi(x_1,x_2) = d(x_1,x_2)$ for all $x_1, x_2 \in \widehat{A}$.

This completes the proof of lemma II.6.2. □

LEMMA II.6.3. *The following is provable in* $\mathsf{RCA}_0$. *Addition, subtraction, multiplication and division are continuous functions from* $\mathbb{R}$ *into* $\mathbb{R}$. *For any* $m \in \mathbb{N}$, *the functions* $\sum_{i=1}^m x_i$, $\prod_{i=1}^m x_i$ *and* $\max(x_1,\dots,x_m)$ *are continuous functions from* $\mathbb{R}^m$ *into* $\mathbb{R}$.

PROOF. For example, let $\Phi$ be such that $(a,r)\Phi(b,s)$ if and only if $(a,r) \in \mathbb{Q} \times \mathbb{Q}^+$ and $(b,s) \in \mathbb{Q} \times \mathbb{Q}^+$ and $b - s < (a+r)^{-1} < (a-r)^{-1} < b + s$ and either $0 < a - r$ or $a + r < 0$. It is straightforward to check that $\Phi$ is a code for a continuous function $\phi$ from $\mathbb{R}$ into $\mathbb{R}$, that $\phi(x) = x^{-1}$ for all nonzero $x \in \mathbb{R}$, and that $\phi(0)$ is undefined. □

LEMMA II.6.4. *The following is provable in* $\mathsf{RCA}_0$. *If* $f\colon \widehat{A} \to \widehat{B}$ *and* $g\colon \widehat{B} \to \widehat{C}$ *are continuous, then so is the composition* $h = gf : \widehat{A} \to \widehat{C}$ *given by* $h(x) = g(f(x))$.

PROOF. Let $F$ and $G$ be the codes of $f : \widehat{A} \to \widehat{B}$ and $g\colon \widehat{B} \to \widehat{C}$ respectively. Let $H$ be such that $(a,r)H(c,t)$ if and only if there exists $(b,s)$ and $s' > s$ such that $(a,r)F(b,s)$ and $(b,s')G(c,t)$. It is straightforward to check that $H$ is a code for a continuous function $h\colon \widehat{A} \to \widehat{C}$ and that $h(x) = g(f(x))$ for all $x \in \widehat{A}$. □

From lemmas II.6.3 and II.6.4 we see that, in $\mathsf{RCA}_0$, any polynomial $f(x_1,\dots,x_m)$ in $m$ indeterminates with coefficients from $\mathbb{R}$ gives rise to a continuous function $f : \mathbb{R}^m \to \mathbb{R}$. The following lemma can be used to show that functions defined by power series, such as $e^x$ and $\sin x$, are also continuous.

LEMMA II.6.5. *The following is provable in* $\mathsf{RCA}_0$. *Let* $\sum_{k=0}^\infty \alpha_k$ *be a convergent series of nonnegative real numbers* $\alpha_k \geq 0$. *Let* $\langle \phi_k : k \in \mathbb{N}\rangle$ *be a sequence of continuous functions* $\phi_k\colon \widehat{A} \to \mathbb{R}$ *such that* $|\phi_k(x)| \leq \alpha_k$ *for all* $k \in \mathbb{N}$ *and* $x \in \widehat{A}$. *Then* $\phi = \sum_{k=0}^\infty \phi_k\colon \widehat{A} \to \mathbb{R}$ *is continuous, and* $|\phi(x)| \leq \sum_{k=0}^\infty \alpha_k$ *for all* $x \in \widehat{A}$.

PROOF. We reason within $\mathsf{RCA}_0$. Let $\Phi$ be such that $(a,r)\Phi(b,s)$ if and only if, for some $m \in \mathbb{N}$, there exist $(a,r)\Phi_k(b_k,s_k)$, $k < m$, such that

$b = \sum_{k<m} b_k$ and

$$\sum_{k=0}^{\infty} s_k + \sum_{k=m}^{\infty} \alpha_k < s.$$

It is straightforward to verify that $\Phi$ is a code for a continuous function $\phi\colon \widehat{A} \to \mathbb{R}$ as required. □

We now specialize to the study of continuous functions on $\mathbb{R}$. We show that the *intermediate value theorem* can be proved within $\mathsf{RCA}_0$. (See also exercise IV.2.12.)

THEOREM II.6.6 (intermediate value theorem). *The following is provable in* $\mathsf{RCA}_0$. *If* $\phi(x)$ *is continuous on the unit interval* $0 \le x \le 1$, *and if* $\phi(0) < 0 < \phi(1)$, *then there exists* $x$ *such that* $0 < x < 1$ *and* $\phi(x) = 0$.

PROOF. We may assume that $\phi(q) \neq 0$ for all rational numbers $q$ with $0 < q < 1$. Then by $\Delta^0_1$ comprehension there exists a set $X$ consisting of all $q \in \mathbb{Q}$ such that $0 < q < 1$ and $\phi(q) < 0$. By primitive recursion using $X$ as a parameter, define a nested sequence of rational intervals

$$(a_0, b_0) = (0, 1),$$

$$(a_{n+1}, b_{n+1}) = \begin{cases} ((a_n + b_n)/2, b_n) & \text{if } \phi((a_n + b_n)/2) < 0, \\ (a_n, (a_n + b_n)/2) & \text{if } \phi((a_n + b_n)/2) > 0. \end{cases}$$

By $\Sigma^0_0$ induction we see that $\phi(a_n) < 0 < \phi(b_n)$ for all $n \in \mathbb{N}$. Also $|a_n - b_n| = 2^{-n}$. Thus $x = \langle a_n : n \in \mathbb{N}\rangle = \langle b_n : n \in \mathbb{N}\rangle$ is a real number. We claim that $\phi(x) = 0$. Suppose not, say $\phi(x) < 0$. Let $\Phi$ be the code of $\phi$. Let $(u, r)\Phi(v, s)$ be such that $|x - u| < r$ and $s < |\phi(x)|/2$. Since $|\phi(x) - v| \le s$, we have $v + s < 0$. Let $n$ be so large that $|b_n - u| < r$. Then $|\phi(b_n) - v| \le s$, hence $\phi(b_n) \le v + s < 0$, a contradiction. This completes the proof. □

COROLLARY II.6.7. *It is provable in* $\mathsf{RCA}_0$ *that the ordered field of real numbers* $\mathbb{R}, +, -, \cdot, 0, 1, <$ *is real closed, i.e., has the intermediate value property for all polynomials.*

PROOF. This is immediate from theorem II.6.6 plus the fact, noted above, that polynomials give rise to continuous functions. □

REMARK II.6.8. Given a continuous real-valued function $\phi(x)$ defined for $0 \le x \le 1$, it is natural to ask whether $\mathsf{RCA}_0$ proves the *maximum principle*. We shall see later that $\mathsf{RCA}_0$ is not even strong enough to prove that the values $\phi(x)$, $0 \le x \le 1$ are bounded above. Even if they are, one cannot prove in $\mathsf{RCA}_0$ that $\sup \phi(x)$ exists. And even if $c = \sup \phi(x)$ exists, one cannot prove that this maximum value is attained, i.e., $\mathsf{RCA}_0$ does not prove the existence of an $x$ such that $\phi(x) = c$. See especially §IV.2.

EXERCISE II.6.9. Within $\mathsf{RCA}_0$, let $\phi\colon \widehat{A} \to \widehat{B}$ be continuous. Show that, given (a code for) an open set $V \subseteq \widehat{B}$, we can effectively find (a code for) an open set $U \subseteq \widehat{A}$ such that for all points $x \in \widehat{A}$, $x \in U$ if and only if $\phi(x) \in V$. Thus we are justified in writing $U = \phi^{-1}(V)$ and in saying that the inverse image of an open set under a continuous function is open.

EXERCISE II.6.10. Within $\mathsf{RCA}_0$, let $\phi\colon \mathbb{R} \to \mathbb{R}$ be continuous. Assume that the derivative

$$\phi'(x) = \lim_{\Delta x \to 0} \frac{\phi(x + \Delta x) - \phi(x)}{\Delta x}$$

exists and is $\leq M$ for all $x \in \mathbb{R}$. Show that

$$\frac{\phi(b) - \phi(a)}{b - a} \leq M$$

for all $x \in \mathbb{R}$.

**Notes for §II.6.** Our concept of continuous function within $\mathsf{RCA}_0$ is the same as that of [236] and Brown/Simpson [27]. Another approach has been taken by Aberth [2] and Bishop, who define continuous functions on the real line to be uniformly continuous on bounded intervals. See for instance Bishop/Bridges [20, page 38]. Thus their approach relies on the fact that the real line is locally compact. Our approach works for complete separable metric spaces which are not required to be locally compact, e.g., the Baire space.

There are considerable differences between Bishop's constructive mathematics and our development of mathematics within the formal system $\mathsf{RCA}_0$. One difference is that Bishop eschews the use of formal systems altogether. A major difference is that Bishop rejects the law of the excluded middle. As a consequence, the intermediate value theorem is not constructively valid in Bishop's sense, even though by II.6.6 it is provable in $\mathsf{RCA}_0$.

Exercise II.6.10 is related to a result of Aberth [2] in recursive analysis. The other results of this section are due to Simpson, unpublished.

## II.7. More on Complete Separable Metric Spaces

In this section we shall prove some additional theorems concerning the topology of complete separable metric spaces, within $\mathsf{RCA}_0$. Throughout this section, we assume that $\widehat{A}$ is a complete separable metric space. For notational convenience, we write $X = \widehat{A}$.

LEMMA II.7.1. *The following is provable in* $\mathsf{RCA}_0$.

1. *Given (a code for) an open set $U \subseteq X$, we can effectively find a (code for a) continuous function $h_U\colon X \to [0,1]$ such that for all $x \in X$, $x \in U$ if and only if $h_U(x) > 0$.*

2. *Conversely, given a (code for a) continuous function $f : X \to \mathbb{R}$, we can effectively find (a code for) an open set $V$ such that for all $x \in X$, $x \in V$ if and only if $f(x) > 0$.*

Proof. For part 1, we put $h_U = \sum_{k \in U} h_k$ where

$$h_k(x) = \frac{\max(0, r - d(a,x))}{r \cdot 2^{k+1}}$$

for all $k = (n, a, r) \in U$ and $x \in X$. The continuity of $h_U$ follows from lemmas II.6.2–II.6.5 since $|h_k| \leq 2^{-k-1}$. It is obvious that $0 \leq h_U \leq 1$, and that $h_U(x) > 0$ if and only if $x \in U$.

For the converse, let $F$ be the code of $f$. Let $\varphi(x)$ be a $\Sigma^0_1$ formula which says that $f(x) > 0$, i.e., there exists $(a, r)F(b, s)$ such that $d(a, x) < r$ and $b - s > 0$. By lemma II.5.7 we get an open set $U \subseteq X$ such that, for all $x \in X$, $x \in U$ if and only if $\varphi(x)$. This completes the proof. □

The following theorem expresses the well known fact that complete separable metric spaces are *paracompact* (see also the notes at end of this section). An *open covering* of $X$ is defined to be a sequence of open sets $\langle U_n : n \in \mathbb{N} \rangle$ in $X$ such that for all $x \in X$ there exists $n \in \mathbb{N}$ such that $x \in U_n$.

Theorem II.7.2 (paracompactness). *The following is provable in* $\mathsf{RCA}_0$. *Given an open covering $\langle U_n : n \in \mathbb{N} \rangle$, we can effectively find an open covering $\langle V_n : n \in \mathbb{N} \rangle$ such that $V_n \subseteq U_n$ for all $n$, and $\langle V_n : n \in \mathbb{N} \rangle$ is* locally finite, *i.e., for all $x \in X$ there exists an open set $W$ such that $x \in W$ and $W \cap V_n = \emptyset$ for all but finitely many $n$.*

Proof. We reason within $\mathsf{RCA}_0$. Let $\langle U_n : n \in \mathbb{N} \rangle$ be an open covering of $X$. By lemma II.7.1.1, we can find a sequence of continuous functions $h_n : X \to [0, 1]$, $n \in \mathbb{N}$, such that for all $x \in X$ and $n \in \mathbb{N}$, $x \in U_n$ if and only if $h_n(x) > 0$. Put

$$g_n = \frac{h_n \cdot 2^{-n}}{\sum_{m \in \mathbb{N}} h_m \cdot 2^{-m}}.$$

Thus $0 \leq g_n \leq 1$, $\sum_{n \in \mathbb{N}} g_n = 1$, and $g_n(x) > 0$ if and only if $x \in U_n$. Thus $\langle g_n : n \in \mathbb{N} \rangle$ is a partition of unity. Put

$$f_n = \min\left(\frac{1}{2}, \sum_{m \leq n} g_m\right) - \min\left(\frac{1}{2}, \sum_{m < n} g_m\right).$$

Thus $0 \leq f_n \leq g_n$ and $\sum_{n \in \mathbb{N}} f_n = 1/2$. Furthermore, for any $x \in X$, $f_n(x) = 0$ for all $n$ such that $\sum_{m<n} g_m(x) > 1/2$. Now to finish the proof, apply lemma II.7.1.2 to get a sequence of open sets $\langle V_n : n \in \mathbb{N} \rangle$ such that for all $x \in X$ and $n \in \mathbb{N}$, $x \in V_n$ if and only if $f_n(x) > 0$. Clearly $\langle V_n : n \in \mathbb{N} \rangle$ has the desired properties. □

The rest of this section is devoted to a proof of the Tietze extension theorem for complete separable metric spaces, within $\mathsf{RCA}_0$. We start with the following version of Urysohn's Lemma.

LEMMA II.7.3 (Urysohn's lemma). *The following is provable in* $\mathsf{RCA}_0$. *Given (codes for) disjoint closed sets $C_0$ and $C_1$ in $X$, we can effectively find a (code for a) continuous function $g\colon X \to [0,1]$ such that, for all $x \in X$ and $i \in \{0,1\}$, $x \in C_i$ if and only if $g(x) = i$.*

PROOF. Let $C_0$ and $C_1$ be given. By lemma II.7.1.1 we can effectively find continuous functions $h_i\colon X \to [0,1]$ such that for all $x \in X$ and $i \in \{0,1\}$, $x \in C_i$ if and only if $h_i(x) = 0$. Define a continuous function $g$ on $X$ by $g = h_0/(h_0 + h_1)$. It is easy to verify that $g$ has the desired properties. □

We shall need the following variant of the previous lemma.

LEMMA II.7.4. *The following is provable in* $\mathsf{RCA}_0$. *Given a closed set $C \subseteq X$ and a continuous function $f\colon C \to [-1,1]$, we can effectively find a continuous function $g\colon X \to [-1/3, 1/3]$ such that $|f(x) - g(x)| \leq 2/3$ for all $x \in C$.*

PROOF. By lemma II.7.1.2, let $U$ be an open set such that for all $x \in X$, $x \in U$ if and only if either $x \notin C$, or $x \in C$ and $f(x) > -1/3$. Similarly let $V$ be an open set such that for all $x \in X$, $x \in V$ if and only if either $x \notin C$, or $x \in C$ and $f(x) < 1/3$. Letting $h_U, h_V\colon X \to [0,1]$ be as in lemma II.7.1.1, define g: $X \to [-1/3, 1/3]$ by

$$g = \frac{1}{3} \cdot \frac{h_U - h_V}{h_U + h_V}.$$

The denominator $h_U + h_V$ is everywhere nonzero since $X = U \cup V$. If $x \in C$ and $f(x) \leq -1/3$, then $x \notin U$ so $h_U(x) = 0$, hence $g(x) = -1/3$. Similarly if $x \in C$ and $f(x) \geq 1/3$, then $g(x) = 1/3$. This proves the lemma. □

The following is our version of the Tietze extension theorem.

THEOREM II.7.5 (Tietze extension theorem). *The following is provable in* $\mathsf{RCA}_0$. *Given a (code for a) closed set $C \subseteq X$ and a (code for a) continuous function $f\colon C \to [-1,1]$, we can effectively find a (code for a) continuous function $g\colon X \to [-1,1]$ such that $g(x) = f(x)$ for all $x \in C$.*

PROOF. We shall first give the construction of $g$, then indicate how to prove within $\mathsf{RCA}_0$ that the construction works.

We begin with $f = f_0\colon C \to [-1,1]$. Apply lemma II.7.4 to get $g_0\colon X \to [-1/3, 1/3]$ such that $|f_0 - g_0| \leq 2/3$ on $C$. Set $f_1 = f_0 - g_0 = f - g_0\colon C \to [-2/3, 2/3]$. Apply lemma II.7.4 again to get $g_1\colon X \to [-2/9, 2/9]$ such that $|f_1 - g_1| \leq 4/9$ on $C$. Set $f_2 = f_1 - g_1 = f - (g_0 + g_1)\colon C \to [-4/9, 4/9]$. . . . . In general, we have

$$f_n = f - (g_0 + g_1 + \cdots + g_{n-1})\colon C \to [-(2/3)^n, (2/3)^n],$$

and the inductive step consists of applying lemma II.7.4 to get $g_n\colon X \to [-2^n/3^{n+1}, 2^n/3^{n+1}]$ such that $|f_n - g_n| \leq (2/3)^{n+1}$ on $C$, then setting $f_{n+1} = f_n - g_n = f - (g_0 + g_1 + \cdots + g_n)\colon C \to [-(2/3)^{n+1}, (2/3)^{n+1}]$. Finally we put $g = \sum_{n=0}^{\infty} g_n\colon X \to [-1, 1]$ which is continuous by lemma II.6.5. It is then clear that $f = g$ on $C$. This completes the construction of $g$.

Within $\mathsf{RCA}_0$, the above construction is to be interpreted as a simultaneous enumeration of the codes of $f_n$ and $g_n$, for all $n \in \mathbb{N}$. The key to showing that the construction works will be to prove the following claim: for all $x \in X$ and all $n$, $g_n(x)$ is defined. Our basic strategy is to try to prove this claim by induction on $n$. Unfortunately the claim is not obviously $\Sigma^0_1$ or $\Pi^0_1$ and so its proof does not obviously go through in $\mathsf{RCA}_0$.

We resolve this difficulty as follows. Tracing back through the construction, we see that $g_n$ is defined from $f_n = f - (g_0 + g_1 + \cdots + g_{n-1})$ by

$$U_n = (X \setminus C) \cup \{x \in C\colon f_n(x) > -(1/3)^{n+1}\},$$

$$V_n = (X \setminus C) \cup \{x \in C\colon f_n(x) < (1/3)^{n+1}\},$$

$$g_n = (1/3)^{n+1} \cdot \frac{h_{U_n} - h_{V_n}}{h_{U_n} + h_{V_n}}.$$

Thus $g_n(x)$ is defined provided the denominator $h_{U_n}(x) + h_{V_n}(x)$ is nonzero, i.e., provided $x$ belongs to the open set $U_n \cup V_n$. And this holds provided either $x \notin C$ or $f_n(x) = f(x) - (g_0(x) + \cdots + g_{n-1}(x))$ is defined. The fact that $U_n$ and $V_n$ are (codes for) open sets is obvious at the outset and does not require a proof by induction on $n$.

So, to prove that $g_n(x)$ is defined for all $x \in X$ and $n \in \mathbb{N}$, we proceed as follows. Fix $x \in X$. Prove by induction on $n$ that $x \in U_n \cup V_n$. This assertion is $\Sigma^0_1$ so we may carry out the inductive argument within $\mathsf{RCA}_0$. The inductive step is as follows. Assume that $x \in U_k \cup V_k$ for all $k < n$. Then, as in the previous paragraph, $g_k(x)$ is defined for all $k < n$. Hence either $x \notin C$ or $f_n(x) = f(x) - (g_0(n) + \cdots + g_{n-1}(x))$ is defined. Hence $x \in U_n \cup V_n$.

This completes the proof. □

**Notes for §II.7.** For general information on metric spaces (paracompactness, Tietze extension theorem, etc.), see e.g., Engelking [52]. The material in this section is due to Simpson, unpublished. For a somewhat more detailed treatment, see Brown [24]. Some alternative versions of the Tietze extension theorem are analyzed in Giusto/Simpson [93].

## II.8. Mathematical Logic

The purpose of this section is to point out that weak versions of some basic results of mathematical logic can be formulated and proved in $\mathsf{RCA}_0$.

A *language* is a set of relation, operation, and constant symbols. We work within $\mathsf{RCA}_0$ and assume a fixed countable language $L$. Terms and formulas of first order logic (i.e., predicate calculus) are defined as usual. We identify terms and formulas with their Gödel numbers under a fixed Gödel numbering. Such a Gödel numbering can be constructed by primitive recursion (theorem II.3.4) using $L$ as a parameter. We can also prove in $\mathsf{RCA}_0$ that there exist sets Trm, Fml, Snt, and Axm consisting of all Gödel numbers of terms, formulas, sentences and logical axioms respectively. We assume that the logical axioms and rules have been set up so that the only logical rule is modus ponens. (See the notes at the end of the section.)

DEFINITION II.8.1 (provability predicate). The following definitions are made in $\mathsf{RCA}_0$. For any set of formulas $X \subseteq \mathrm{Fml}$, let $\mathrm{Prf}(X, p)$ be the $\Sigma^0_0$ formula which says that $p$ is a *proof from* $X$, i.e., $p \in \mathrm{Seq} \wedge \forall k\,(k < \mathrm{lh}(p) \to p(k) \in \mathrm{Fml}) \wedge \forall k\,(k < \mathrm{lh}(p) \to (p(k) \in X \vee p(k) \in \mathrm{Axm} \vee (\exists i < k)\,(\exists j < k)\,(p(i) = (p(j) \to p(k)))))$. We say that $\varphi$ is *provable from* $X$ (written $\mathrm{Pbl}(X, \varphi)$) if $\exists p\,(\mathrm{Prf}(X, p) \wedge (\exists i < \mathrm{lh}(p))\,(p(i) = \varphi))$. Note that the formula $\mathrm{Pbl}(X, \varphi)$ is $\Sigma^0_1$.

DEFINITION II.8.2 (consistency, etc.). The following definitions are made in $\mathsf{RCA}_0$. A set $X \subseteq \mathrm{Snt}$ is *consistent* if $\neg\exists\varphi\,(\mathrm{Pbl}(X, \varphi) \wedge \mathrm{Pbl}(X, \neg\varphi))$. $X$ is *closed under logical consequence* if $\forall\sigma\,((\sigma \in \mathrm{Snt} \wedge \mathrm{Pbl}(X, \sigma)) \to \sigma \in X)$. $X$ is *complete* if $\forall\sigma\,(\sigma \in \mathrm{Snt} \to (\mathrm{Pbl}(X, \sigma) \vee \mathrm{Pbl}(X, \neg\sigma)))$.

DEFINITION II.8.3 (models). The following definition is made in $\mathsf{RCA}_0$. A *countable model* is a function $M\colon \mathrm{T}_M \cup \mathrm{S}_M \to |M| \cup \{0, 1\}$. Here $|M| \subseteq \mathbb{N}$ is a set called the *universe* of $M$, and $\mathrm{T}_M$ and $\mathrm{S}_M$ are respectively the sets of closed terms and sentences of the expanded language $L_M = L \cup \{\underline{m}\colon m \in |M|\}$ with new constant symbols $\underline{a}$ for each element $a$ of $|M|$. The function $M$ is required to obey the familiar clauses of Tarski's truth definition:

1. $t \in \mathrm{T}_M$ implies $M(t) \in |M|$;
2. $\sigma \in \mathrm{S}_M$ implies $M(\sigma) \in \{0, 1\}$;
3. for any $t_1, t'_1, \ldots, t_n, t'_n \in \mathrm{T}_M$, if $M(t_i) = M(t'_i)$, $1 \le i \le n$, then $M(\underline{R}(t_1, \ldots, t_n)) = M(\underline{R}(t'_1, \ldots, t'_n))$ and $M(\underline{o}(t_1, \ldots, t_n)) = M(\underline{o}(t'_1, \ldots, t'_n))$; here $\underline{R}$ is a relation symbol and $\underline{o}$ is a function symbol;
4. $M(\neg\sigma) = 1 - M(\sigma)$;
5. $M(\sigma_1 \wedge \sigma_2) = M(\sigma_1) \cdot M(\sigma_2)$;
6. $M(\forall v\,\varphi(v)) = \prod_{a \in |M|} M(\varphi(\underline{a}))$;

etc.

The following is a weak version of Gödel's completeness theorem.

THEOREM II.8.4 (weak completeness theorem). *The following is provable in* $\mathsf{RCA}_0$. *Let* $X \subseteq \mathrm{Snt}$ *be consistent and closed under logical consequence. Then there exists a countable model* $M$ *such that* $M(\sigma) = 1$ *for all* $\sigma \in X$.

PROOF. We first prove a weak version of Lindenbaum's lemma.

LEMMA II.8.5 (weak Lindenbaum lemma). *The following is provable in* $\mathsf{RCA}_0$. *Suppose* $X \subseteq \mathrm{Snt}$ *is consistent and closed under logical consequence. Then there exists* $X^* \subseteq \mathrm{Snt}$ *such that* $X \subseteq X^*$ *and* $X^*$ *is consistent, complete, and closed under logical consequence.*

PROOF. Let $\langle \sigma_n : n \in \mathbb{N} \rangle$ be a one-to-one enumeration of Snt. Define a sequence of sentences $\langle \sigma_n^* : n \in \mathbb{N} \rangle$ by primitive recursion as follows: $\sigma_n^* = \sigma_n$ if $((\sigma_0^* \wedge \cdots \wedge \sigma_{n-1}^*) \to \sigma_n) \in X$; $\sigma_n^* = \neg\sigma_n$ otherwise. Let $X^*$ be the set of all $\sigma_n^*$, $n \in \mathbb{N}$. Clearly $X^*$ has the desired properties. The lemma is proved. □

Now to prove theorem II.8.4, let $C$ be an infinite set of new constant symbols. Let $\langle \underline{c}_n : n \in \mathbb{N} \rangle$ be a one-to-one enumeration of $C$ and let $\langle \varphi_n(x) : n \in \mathbb{N} \rangle$ be an enumeration of all formulas with one free variable in the expanded language $L_1 = L \cup C$. We may safely assume that $\underline{c}_n$ does not occur in $\varphi_i(x)$, $i < n$. If $\tau$ is any $\mathrm{L}_1$-sentence, we write

$$\tau^- \equiv \forall z_0 \cdots \forall z_n \, \tau(z_0/\underline{c}_0, \ldots, z_n/\underline{c}_n)$$

where

$$n = n_\tau = \sup\{n : \underline{c}_n \text{ occurs in } \tau\}$$

and $z_0, \ldots, z_n$ are new variables. Thus $\tau^-$ is an $L$-sentence. Form Henkin axioms

$$\eta_n \equiv (\exists x \, \varphi_n(x)) \to \varphi_n(\underline{c}_n)$$

and let $X_1$ be the set of all sentences of $L_1$ which are provable from $X$ plus the Henkin axioms. $X_1$ exists by $\Delta_1^0$ comprehension since

$$\sigma \in X_1 \leftrightarrow ((\eta_0 \wedge \cdots \wedge \eta_n) \to \sigma)^- \in X$$

where $n = n_\sigma$. Clearly $X_1$ is consistent and closed under logical consequence, so by lemma II.8.5 let $X_1^*$ be a completion of $X_1$. A countable model $M$ can be read off from $X_1^*$ in the usual way. Namely, let $|M|$ be the set of all $\underline{c}_n \in C$ such that $\neg\exists m \, (m < n \wedge (\underline{c}_m = \underline{c}_n) \in X_1^*)$. For all $\sigma \in \mathrm{S}_M$ put $M(\sigma) = 1$ if and only if $\sigma \in X_1^*$. This completes the proof of theorem II.8.4. □

COROLLARY II.8.6. *The following is provable in* $\mathsf{RCA}_0$. *If* $X \subseteq \mathrm{Snt}$ *is consistent and complete, then there exists a countable model* $M$ *such that* $M(\sigma) = 1$ *for all* $\sigma \in X$.

PROOF. The hypotheses on $X$ imply that for all $\sigma \in \mathrm{Snt}$,

$$\mathrm{Pbl}(X, \sigma) \leftrightarrow \neg \mathrm{Pbl}(X, \neg\sigma).$$

Hence by $\Delta^0_1$ comprehension there exists a set $\mathrm{Pbl}_X$ consisting of all sentences which are provable from $X$. The corollary is proved by applying theorem II.8.5 to $\mathrm{Pbl}_X$. □

REMARK II.8.7. In connection with the above theorem and corollary, note that it is not provable in $\mathsf{RCA}_0$ that every consistent set of sentences can be extended to a consistent set of sentences which is closed under logical consequence. For example, let Q be the set of axioms of Robinson's system. (See the notes at end of section.) Then Q is finite but, as is well known, there is no recursive consistent set of sentences which contains Q and is closed under logical consequence. Thus the $\omega$-model REC satisfies "Q is consistent but has no countable model." In chapter IV we shall see that $\mathsf{WKL}_0$ is strong enough to prove the full Gödel completeness theorem: Every consistent set of sentences in a countable language has a countable model.

We now consider converses of the Gödel completeness theorem. The following version of the soundness theorem is easy to prove.

THEOREM II.8.8 (soundness theorem). *The following is provable in* $\mathsf{RCA}_0$. *If* $X \subseteq \mathrm{Snt}$ *and there exists a countable model* $M$ *such that* $M(\sigma) = 1$ *for all* $\sigma \in X$, *then* $X$ *is consistent*.

PROOF. For any formula $\varphi$ let $\overline{\varphi}$ be the *universal closure* of $\varphi$, i.e., the sentence obtained by prefixing $\varphi$ with universal quantifiers. Given $p$ such that $\mathrm{Prf}(X, p)$, it is straightforward to prove by induction on $k < \mathrm{lh}(p)$ that $M\left(\overline{p(k)}\right) = 1$. This implies the theorem. □

For later use we prove the following stronger version of the soundness theorem.

DEFINITION II.8.9 (weak models). Within $\mathsf{RCA}_0$, let $X \subseteq \mathrm{Snt}$ be a set of sentences. A *weak countable model of* $X$ is a function $M : \mathrm{T}_M \cup \mathrm{S}^X_M \to |M| \cup \{0, 1\}$. Here $|M|$ and $\mathrm{T}_M$ are as in definition II.8.3, and $\mathrm{S}^X_M$ is the set of all $\sigma \in \mathrm{S}_M$ such that $\sigma$ is a propositional combination of substitution instances of subformulas of elements of $X$. We require $M$ to obey the clauses of definition II.8.3 except that the clause involving $\forall v\, \varphi(v)$ applies only when $\forall v\, \varphi(v) \in \mathrm{S}^X_M$. We also require that $M(\sigma) = 1$ whenever $\sigma \in X$.

THEOREM II.8.10 (strong soundness theorem). *The following is provable in* $\mathsf{RCA}_0$. *If there exists a weak countable model of* $X \subseteq \mathrm{Snt}$, *then* $X$ *is consistent*.

PROOF. Consider a cut-free system of axioms and rules for logic (see notes at end of section). In $\mathsf{RCA}_0$ we can carry out the usual syntactical

proof that if $\varphi$ is provable from the empty set (in the sense of definition II.8.1), then there exists a cut-free proof of $\varphi$. This cut-free proof has the property that each formula occurring in it is a substitution instance of a subformula of $\varphi$.

Assume now that $M$ is a weak countable model of $X \subseteq \mathrm{Snt}$, but $X$ is not consistent. Then there exists $\sigma_1, \ldots, \sigma_n \in X$ such that $\neg(\sigma_1 \wedge \cdots \wedge \sigma_n)$ is provable from the empty set. Let $p$ be a cut-free proof of $\neg(\sigma_1 \wedge \cdots \wedge \sigma_n)$. Then $\mathrm{S}_M^X$ contains all $\sigma \in \mathrm{S}_M$ which are substitution instances of formulas in $p$. By $\Pi_1^0$ induction on the length of $p$ we can prove that $M(\sigma) = 1$ for all such $\sigma$. In particular $M(\neg(\sigma_1 \wedge \cdots \wedge \sigma_n)) = 1$, but this is impossible since $M(\sigma_1) = \cdots = M(\sigma_n) = 1$. The proof is complete. □

In order to illustrate the significance of the above result, we present the following application. Let $L = \mathrm{L}_1(\exp)$ be the language of first order arithmetic $+, \cdot, 0, 1, <, =$ augmented by a binary operation symbol $\exp(m, n) = m^n$ intended to denote exponentiation. Let EFA (elementary function arithmetic) consist of the basic axioms (definition I.2.4) augmented by

$$m^0 = 1, \quad m^{n+1} = m^n \cdot m,$$

plus $\Sigma_0^0$ induction.

Theorem II.8.11 (consistency of EFA). $\mathsf{RCA}_0$ *proves the consistency of* EFA.

Proof. We reason within $\mathsf{RCA}_0$. Let EFA′ be the same as EFA with the $\Sigma_0^0$ induction scheme

$$(\theta(0) \wedge \forall n\,(\theta(n) \to \theta(n+1))) \to \forall n\,\theta(n)$$

replaced by the equivalent scheme

$$\forall n\,((\theta(0) \wedge \forall k < n\,(\theta(k) \to \theta(k+1))) \to \theta(n)).$$

Here $\theta(n)$ denotes an arbitrary $\Sigma_0^0$ formula in the language of EFA. Let $X$ be the set of all universal closures of axioms of EFA′. In order to show that EFA is consistent, it suffices to prove the consistency of EFA′, i.e., of $X$. And for this it suffices by theorem II.8.10 to construct a weak countable model $M$ of $X$.

We begin by letting $|M| = \mathbb{N}$. Note that $X$ consists of $\Pi_1^0$ sentences; this is why we switched from EFA to EFA′. Let $\mathrm{T}_M$ and $\mathrm{S}_M^X$ be as in definition II.8.9. Let $\mathrm{S}_M^-$ be the set of all $\Sigma_0^0$ sentences in the language of EFA with parameters from $|M|$. Note that $\mathrm{S}_M^- \subseteq \mathrm{S}_M^X$. Using primitive recursion (theorem II.3.4), it is straightforward to prove the existence of a function

$$M^-\colon \mathrm{T}_M \cup \mathrm{S}_M^- \to |M| \cup \{0, 1\}$$

obeying the Tarski clauses. Since $X$ consists of $\Pi_1^0$ sentences, it is trivial to extend $M^-$ to a function

$$M\colon \mathrm{T}_M \cup \mathrm{S}_M^X \to |M| \cup \{0, 1\}$$

which also obeys the Tarski clauses. It is then easy to check that $M(\sigma) = 1$ for each $\sigma \in X$. This completes the proof. □

**Notes for §II.8.** In definition II.8.1 we assumed that the logical axioms and rules had been set up so that the only rule is modus ponens. For one way to do this, see Enderton [51, §2.4]. Theorem II.8.4 applied to the $\omega$-model REC implies that every recursively decidable theory has a recursive model with a recursive satisfaction predicate. This result is originally due to Morley and is the beginning of a subject known as *recursive model theory*. For a recent survey of recursive model theory, see [53]. The original source of Robinson's system Q is Tarski/Mostowski/Robinson [266]. The proof of theorem II.8.10 used a cut-free system of logical axioms and rules, for which see e.g., Kleene [142].

The material in this section is due to Simpson, unpublished.

## II.9. Countable Fields

In this section we show that some of the usual constructions of countable algebraic structures can be carried out in $\mathsf{RCA}_0$.

Definition II.9.1 (fields). The following definitions are made in $\mathsf{RCA}_0$. A *countable field* $K$ consists of a set $|K| \subseteq \mathbb{N}$ together with binary operations $+_K$, $\cdot_K$ and a unary operation $-_K$ and distinguished elements $0_K$, $1_K$ such that the system $|K|, +_K, -_K, \cdot_K, 0_K, 1_K$ obeys the usual field axioms, e.g., $\forall x \, \forall y \, (x \cdot y = y \cdot x)$ and $\forall x \, (x \neq 0 \to \exists y \, (x \cdot y = 1))$. The *polynomial ring* $K[x]$ consists of all finite sequences $\langle a_0, \ldots, a_n \rangle$ of elements of $|K|$ such that $n = 0$ or $a_n \neq 0$. We denote $\langle a_0, \ldots, a_n \rangle$ by $\sum_{i=0}^{n} a_i x^i$.

The theory of finite extensions of a countable field can be developed as usual within $\mathsf{RCA}_0$. As usual, a countable field $K$ is said to be *algebraically closed* if for all nonconstant polynomials $f(x) \in K[x]$ there exists $a \in K$ such that $f(a) = 0$.

Definition II.9.2 (algebraic closure). The following definition is made in $\mathsf{RCA}_0$. Let $K$ be a countable field. An *algebraic closure* of $K$ consists of an algebraically closed countable field $\widetilde{K}$ together with a monomorphism $h\colon K \to \widetilde{K}$ such that for all $b \in \widetilde{K}$ there exists a nonzero polynomial $f(x) \in K[x]$ such that $h(f)(b) = 0$. Here for $f(x) = \sum_{i=0}^{n} a_i x^i \in K[x]$ we write $h(f)(x) = \sum_{i=0}^{n} h(a_i) x^i \in \widetilde{K}[x]$. (Caution: We cannot prove in $\mathsf{RCA}_0$ that there exists a set which is the image of the monomorphism $h\colon K \to \widetilde{K}$. See §III.3.)

In order to prove that every countable field has an algebraic closure, we shall invoke the model-theoretic results which were presented in the

previous section. Let $L$ be the language of fields with symbols $+, -, \cdot, 0, 1$. Let AF be the usual set of field axioms, e.g., $\forall x\,(x \neq 0 \to \exists y\,(x \cdot y = 1))$. Let ACF be the usual set of axioms for an algebraically closed field: ACF consists of AF plus the infinite set of axioms

$$\forall x_0 \cdots \forall x_{n-1}\,\exists y\,(y^n + x_{n-1}y^{n-1} + \cdots + x_1 y + x_0 = 0)$$

for all $n \in \mathbb{N}$, $n \geq 1$.

Lemma II.9.3. *The following facts are provable in* $\mathsf{RCA}_0$. (i) ACF *admits elimination of quantifiers, i.e., for any formula* $\varphi$ *there exists a quantifier-free formula* $\varphi^*$ *such that* ACF *proves* $\varphi \leftrightarrow \varphi^*$. (ii) *For any quantifier-free formula* $\varphi$, *if* ACF *proves* $\varphi$ *then* AF *proves* $\varphi$.

Proof. These well known results have purely syntactical proofs which can be transcribed into $\mathsf{RCA}_0$, using the availability of various primitive recursive functions and predicates. (See the notes at end of this section.) □

Theorem II.9.4 (existence of algebraic closure). *It is provable in* $\mathsf{RCA}_0$ *that every countable field* $K$ *has an algebraic closure.*

Proof. Let $\Delta_K$ be the *quantifier-free diagram* of $K$, i.e., the set of all quantifier-free sentences of $L_K$ which are true in $K$. Clearly $K$ can be expanded to a weak countable model of $\Delta_K \cup$ AF. Hence by theorem II.8.10, $\Delta_K \cup$ AF is consistent. It follows by lemma II.9.3(ii) that $\Delta_K \cup$ ACF is consistent. Also $\Delta_K \cup$ ACF is complete by lemma II.9.3(i). Hence by corollary II.8.6 there exists a countable model $M$ of $\Delta_K \cup$ ACF. Clearly $M$ may be viewed as a countable algebraically closed field and there is a canonical embedding $k\colon K \to M$. Let $\varphi(b)$ be a $\Sigma^0_1$ formula saying that $b \in |M|$ and there exists a nonconstant $f(x) \in K[x]$ such that $k(f)(b) = 0$. By lemma II.3.7 there exists a one-to-one function $g\colon \mathbb{N} \to |M|$ such that for all $b \in |M|$, $\varphi(b)$ if and only if $\exists j\,(g(j) = b)$. Put $|\widetilde{K}| = \mathbb{N}$ and define the field operations of $\widetilde{K}$ by pulling back via $g$, e.g., $i +_{\widetilde{K}} j = g^{-1}(g(i) +_M g(j))$. Clearly $\widetilde{K}$ is an algebraic closure of $K$ with the monomorphism $h\colon K \to \widetilde{K}$ given by $h(a) = g^{-1}(k(a))$. This completes the proof. □

Definition II.9.5 (real closure). The following definitions are made in $\mathsf{RCA}_0$. A *countable ordered field* consists of a countable field $K$ together with a binary relation $<_K \subseteq |K|^2$ such that $K, <_K$ obeys the usual ordered field axioms, e.g., $\forall x\,\forall y\,(x < y \vee x = y \vee y < x)$ and $(x < y \leftrightarrow x + z < y + z)$. A countable ordered field is said to be *real closed* if it has the intermediate value property for polynomials, i.e., for all $g(x) \in K[x]$ and $a, b \in K$, if $g(a) < 0 < g(b)$ then there exists $c \in K$ between $a$ and $b$ such that $g(c) = 0$. A *real closure* of a countable ordered field $K$ consists of a countable real closed ordered field $\overline{K}$ together with a

monomorphism $h\colon K \to \overline{K}$ such that for each $b \in \overline{K}$ there exists a nonconstant $f(x) \in K[x]$ such that $h(f)(b) = 0$.

Our proof that every countable ordered field has a real closure will be similar to the above proof of the corresponding result for algebraic closure. Let $L$ be the language of ordered fields and let OF be the set of ordered field axioms. Let RCOF be the set of real closed ordered field axioms, i.e., RCOF consists of OF plus the axioms

$$\forall x_0 \cdots \forall x_n \, \forall u \, \forall v \, ((u < v \wedge x_n \cdot u^n + \cdots + x_0 < 0 < x_n \cdot v^n + \cdots + x_0) \\ \to \exists w \, (u < w < v \wedge x_n \cdot w^n + \cdots + x_0 = 0))$$

for all $n \in \mathbb{N}$.

LEMMA II.9.6. *The following facts are provable in* $\mathsf{RCA}_0$. (i) RCOF *admits elimination of quantifiers.* (ii) *For any quantifier-free formula* $\varphi$, *if* RCOF *proves* $\varphi$ *then* OF *proves* $\varphi$.

PROOF. The well known syntactical proofs of these results can be carried out in $\mathsf{RCA}_0$. (See the notes at end of this section.) □

THEOREM II.9.7 (existence and uniqueness of real closure). *The following is provable in* $\mathsf{RCA}_0$. *Every countable ordered field* $K$ *has a real closure. The real closure is unique in the sense that, if* $h_1\colon K \to \overline{K}_1$ *and* $h_2\colon K \to \overline{K}_2$ *are two real closures of* $K$, *there exists a unique isomorphism* $h\colon \overline{K}_1 \to \overline{K}_2$ *of* $\overline{K}_1$ *onto* $\overline{K}_2$ *such that* $h(h_1(a)) = h_2(a)$ *for all* $a \in K$.

PROOF. The proof of the existence of a real closure is similar to the proof of theorem II.9.4 relying now on lemma II.9.6 instead of lemma II.9.3. The uniqueness follows from the fact that for each $b_1 \in \overline{K}_1$ there exists an ordered pair $(f, i)$ such that $f \in K[x]$ and $b_1$ is the unique $b \in \overline{K}_1$ such that $h_1(f)(b) = 0$ and there are exactly $i$ elements $a \in \overline{K}_1$ such that $a < b$ and $h_1(f)(a) = 0$. By quantifier elimination there is a unique corresponding element $b_2 \in \overline{K}_2$ and this gives the isomorphism. □

REMARKS II.9.8. (1) There is no analogous uniqueness result for algebraic closure. We shall see later (§IV.5) that $\mathsf{RCA}_0$ does not prove that the algebraic closure of a countable field is unique. (2) A countable field $K$ is said to be *formally real* if the equations $x_1^2 + \cdots + x_n^2 = -1$, $n \in \mathbb{N}$, have no solution in $K$. There is a well known theorem due to Artin and Schreier which states that every formally real field is orderable. We shall see later (§IV.4) that this theorem for countable formally real fields is not provable in $\mathsf{RCA}_0$.

**Notes for §II.9.** For a somewhat different treatment of the material in this section, see Friedman/Simpson/Smith [78]. In proving lemmas II.9.3 and II.9.6, we used Tarski's syntactical quantifier elimination methods as presented, e.g., in Kreisel/Krivine [152]. If we specialize theorem II.9.4 to the $\omega$-model REC, we obtain a result which is originally due to Rabin:

every recursive field has a recursive algebraic closure. This is one of the first theorems of a subject known as *recursive algebra*. For a recent survey of recursive algebra, see [53].

## II.10. Separable Banach Spaces

In this section we show that some rudimentary portions of the theory of separable Banach spaces can be developed within $\mathsf{RCA}_0$. The techniques of this section are based on those of §§II.5 and II.6.

Let $K$ be a countable field. Within $\mathsf{RCA}_0$, a *countable vector space* $A$ over $K$ consists of a set $|A| \subseteq \mathbb{N}$ together with operations $+\colon |A| \times |A| \to |A|$ and $\cdot\colon |K| \times |A| \to |A|$ and a distinguished element $0 \in |A|$, such that $|A|, +, \cdot, 0$ satisfy the usual axioms for a vector space over $K$.

Definition II.10.1 (separable Banach spaces). Within $\mathsf{RCA}_0$, we define a (code for a) *separable Banach space* $\widehat{A}$ to consist of a countable vector space $A$ over the rational field $\mathbb{Q}$ together with a sequence of real numbers $\|\ \|\colon A \to \mathbb{R}$ satisfying

(i) $\|q \cdot a\| = |q| \cdot \|a\|$ for all $q \in \mathbb{Q}$ and $a \in A$;
(ii) $\|a + b\| \leq \|a\| + \|b\|$ for all $a, b \in A$.

A *point of* $\widehat{A}$ is defined to be a sequence $\langle a_k\colon k \in \mathbb{N}\rangle$ of elements of $A$ such that $\|a_k - a_{k+1}\| \leq 2^{-k-1}$ for all $k \in \mathbb{N}$.

Thus a code for a separable Banach space is simply a countable pseudo-normed vector space over the rationals. As usual we define a pseudometric on $A$ by $d(a,b) = \|a - b\|$, for all $a, b \in A$. Thus $\widehat{A}$ is the complete separable metric space which is the completion of $A$ under $d$, as in §II.5.

If $x = \langle a_k\colon k \in \mathbb{N}\rangle$ and $y = \langle b_k\colon k \in \mathbb{N}\rangle$ are points of $\widehat{A}$ and $\alpha = \langle q_k\colon k \in \mathbb{N}\rangle$ is a real number, we define $\|x\| = \lim_k \|a_k\|$, $x + y = \lim_k (a_k + b_k)$, and $\alpha \cdot x = \lim_k (q_k \cdot a_k)$. It is easy to show within $\mathsf{RCA}_0$ that these limits exist and that $\|\ \|\colon \widehat{A} \to \mathbb{R}$, $+\colon \widehat{A} \times \widehat{A} \to \widehat{A}$ and $\cdot\colon \mathbb{R} \times \widehat{A} \to \widehat{A}$ are continuous, etc. Thus $\widehat{A}$ enjoys the usual properties of a normed vector space over $\mathbb{R}$. In addition $\widehat{A}$ is separable in the sense of definition II.5.1 and complete in the sense of exercise II.5.2. Thus we are justified in referring to $\widehat{A}$ within $\mathsf{RCA}_0$ as a separable Banach space.

We shall now present three examples of separable Banach spaces within $\mathsf{RCA}_0$: $\ell_p$, $\mathrm{C}[0,1]$, and $\mathrm{L}_p[0,1]$.

For all three examples we shall use the same underlying countable vector space $A$ over $\mathbb{Q}$. Within $\mathsf{RCA}_0$, we define $|A| \subseteq \mathbb{N}$ to be the set of (codes for) nonempty finite sequences of rational numbers $\langle r_0, \ldots, r_m\rangle$ such that either $m = 0$ or $r_m \neq 0$. Addition on $|A|$ is defined by putting $\langle r_0, \ldots, r_m\rangle + \langle s_0, \ldots, s_n\rangle = \langle r_0 + s_0, \ldots, r_k + s_k\rangle$ where $r_i, s_i = 0$ for $i > m, n$ respectively, and $k = \max\{i\colon i = 0 \vee r_i + s_i \neq 0\}$. For scalar

multiplication on $|A|$, we put $q\cdot\langle r_0,\dots,r_m\rangle = \langle 0\rangle$ if $q = 0$, $\langle q\cdot r_0,\dots,q\cdot r_m\rangle$ if $0 \neq q \in \mathbb{Q}$. It is then easily verified that $A$ is a vector space over $\mathbb{Q}$. (This is the same as the vector space $V_0$ of §III.4.)

EXAMPLE II.10.2 (the Banach spaces $\ell_p$, $1 \leq p < \infty$). We define an $\mathsf{RCA}_0$ version of the $\ell_p$ spaces. Fix a real number $p$ such that $1 \leq p < \infty$. Let $A$ be as above. For all $\langle r_0,\dots,r_m\rangle \in |A|$, put

$$\|\langle r_0,\dots,r_m\rangle\| = \left(\sum_{i=0}^{m} |r_i|^p\right)^{1/p}.$$

Thus $A$ becomes a code for a separable Banach space $\widehat{A}$ and we define $\ell_p = \widehat{A}$.

It can be shown in $\mathsf{RCA}_0$ that the points of $\ell_p$ are in canonical one-to-one correspondence with the sequences $\langle x_i : i \in \mathbb{N}\rangle$, $x_i \in \mathbb{R}$, such that $\sum_{i=0}^{\infty} |x_i|^p$ converges. This correspondence is norm-preserving, so our $\ell_p = \widehat{A}$ can be identified with the usual $\ell_p$ sequence space as defined in Banach space textbooks.

EXAMPLE II.10.3 (the Banach space C[0, 1]). We define an $\mathsf{RCA}_0$ version of the space of continuous real-valued functions C[0, 1]. Let $A, +, \cdot$ be as in the previous example. For $\langle r_0,\dots,r_m\rangle \in A$, define

$$\|\langle r_0,\dots,r_m\rangle\| = \sup_{0\leq x\leq 1} |r_m x^m + r_{m-1}x^{m-1} + \cdots + r_1 x + r_0|.$$

We define $\mathrm{C}[0,1] = \widehat{A}$, the completion of $A$ under the metric induced by this norm. Thus C[0, 1] is a separable Banach space.

We would like to be able to assert that the points of our C[0, 1] are in canonical one-to-one correspondence with the continuous real-valued functions on the closed unit interval [0, 1]. Unfortunately, the axioms of $\mathsf{RCA}_0$ are not strong enough to prove this. This situation will be clarified in §IV.2 when we discuss the Weierstraß approximation theorem. There we shall see that points of our C[0, 1] are in canonical one-to-one correspondence with continuous real-valued functions on [0, 1] having a modulus of uniform continuity. See also the generalization to compact metric spaces in exercise IV.2.13.

EXAMPLE II.10.4 (the Banach spaces $\mathrm{L}_p[0,1]$, $1 \leq p < \infty$). We define an $\mathsf{RCA}_0$ version of the familiar spaces $\mathrm{L}_p[0,1]$, $1 \leq p < \infty$. Again let $A$ be as in example II.10.2. For $\langle r_0,\dots,r_m\rangle \in A$ define

$$\|\langle r_0,\dots,r_m\rangle\| = \left(\int_0^1 |r_m x^m + r_{m-1}x^{m-1} + \cdots + r_1 x + r_0|^p\, dx\right)^{1/p}.$$

Our use of the Riemann integral here will be justified in §IV.2. Under the above norm $A$ again becomes a code for a separable Banach space $\widehat{A}$, and

we define $\mathrm{L}_p[0,1] = \widehat{A}$. See also the generalization to compact metric spaces in exercise IV.2.15.

Unfortunately, $\mathsf{RCA}_0$ is not strong enough to prove that the points of our $\mathrm{L}_p[0,1]$ are in canonical one-to-one correspondence with $p$th power absolutely integrable measurable functions on $[0,1]$. Stronger axioms are needed in order to prove this. See also remark X.1.11 and the notes at the end of §IV.2.

We now discuss bounded linear operators.

Definition II.10.5 (bounded linear operators). The following definition is made in $\mathsf{RCA}_0$. Let $\widehat{A}$ and $\widehat{B}$ be separable Banach spaces. A (code for a) *bounded linear operator* from $\widehat{A}$ to $\widehat{B}$ is a sequence $F : A \to \widehat{B}$ of points of $\widehat{B}$, indexed by elements of $A$, such that (i) $F(q_1a_1 + q_2a_2) = q_1F(a_1) + q_2F(a_2)$ for all $q_1, q_2 \in \mathbb{Q}$ and $a_1, a_2 \in A$, (ii) there exists a real number $\alpha$ such that $\|F(a)\| \leq \alpha \cdot \|a\|$ for all $a \in A$.

For $F$ and $\alpha$ as above and $x = \langle a_k : k \in \mathbb{N} \rangle \in \widehat{A}$, we define $F(x) = \lim_k F(a_k)$. Thus $\|F(x)\| \leq \alpha \cdot \|x\|$ for all $x \in \widehat{A}$. We write $F : \widehat{A} \to \widehat{B}$ to denote this state of affairs. If $\alpha \in \mathbb{R}$ is such that $\|F(x)\| \leq \alpha \cdot \|x\|$ for all $x \in \widehat{A}$, we write $\|F\| \leq \alpha$.

We now proceed to show within $\mathsf{RCA}_0$ that bounded linear operators are the same thing as continuous linear operators.

Definition II.10.6 (continuous linear operators). The following definition is made in $\mathsf{RCA}_0$. Let $\widehat{A}$ and $\widehat{B}$ be separable Banach spaces. A *continuous linear operator* from $\widehat{A}$ to $\widehat{B}$ is a totally defined continuous function $\phi : \widehat{A} \to \widehat{B}$ (in the sense of §II.6) such that

$$\phi(\alpha_1 x_1 + \alpha_2 x_2) = \alpha_1 \phi(x_1) + \alpha_2 \phi(x_2)$$

for all $\alpha_1, \alpha_2 \in \mathbb{R}$ and $x_1, x_2 \in \widehat{A}$.

Theorem II.10.7. *The following is provable in* $\mathsf{RCA}_0$. *Given a continuous linear operator* $\phi : \widehat{A} \to \widehat{B}$, *there exists a bounded linear operator* $F : \widehat{A} \to \widehat{B}$ *such that*

$$F(x) = \phi(x) \quad \text{for all } x \in \widehat{A}. \tag{5}$$

*Conversely, given a bounded linear operator* $F : \widehat{A} \to \widehat{B}$, *there exists a continuous linear operator* $\phi : \widehat{A} \to \widehat{B}$ *such that* (5) *holds.*

Proof. Given a continuous linear operator $\phi : \widehat{A} \to \widehat{B}$, let $\Phi$ be a code for $\phi$ and define $F : A \to \widehat{B}$ by $F(a) = \phi(a)$, for all $a \in A$. Clearly $F$ is $\mathbb{Q}$-linear, i.e., satisfies condition II.10.5(i). To see that $F$ is bounded, note that $\phi(0) = 0$, hence $(0, r)\Phi(0, 1)$ for some $r \in \mathbb{Q}^+$. Thus, for any $x \in \widehat{A}$, $\|x\| < r$ implies $\|\phi(x)\| \leq 1$. Therefore $\|F(a)\| \leq \|a\|/r$ for all $a \in A$, so $F$ satisfies II.10.5(ii) with $\alpha = 1/r$. Thus $F : \widehat{A} \to \widehat{B}$ is a bounded linear operator, and it is easy to check that (5) holds.

For the converse, assume that $F: A \to \widehat{B}$ is the code of a bounded linear operator $F: \widehat{A} \to \widehat{B}$ with $\|F\| \leq \alpha$. Let $\varphi(a, r, b, s)$ be a $\Sigma^0_1$ formula saying that $a \in A$, $b \in B$, $r \in \mathbb{Q}^+$, $s \in \mathbb{Q}^+$, and $(F(a), r\alpha) < (b, s)$, i.e., $\|F(a) - b\| < s - r\alpha$. Write $\varphi(a, r, b, s) \equiv \exists n\, \theta(n, a, r, b, s)$ where $\theta$ is $\Sigma^0_0$. By $\Sigma^0_0$ comprehension let $\Phi$ be the set of all $(n, a, r, b, s) \in \mathbb{N} \times A \times \mathbb{Q}^+ \times B \times \mathbb{Q}^+$ such that $\theta(n, a, r, b, s)$ holds. It is straightforward to verify that $\Phi$ is a code of a totally defined continuous function $\phi: \widehat{A} \to \widehat{B}$ and that (5) holds.

This completes the proof. □

We now prove an $\mathsf{RCA}_0$ version of one of the most famous theorems in Banach space theory, known as the *Banach/Steinhaus theorem* or the *uniform boundedness principle*. The proof uses our $\mathsf{RCA}_0$ version of the Baire category theorem, which was proved in §II.5.

THEOREM II.10.8 (Banach/Steinhaus theorem). *The following is provable in* $\mathsf{RCA}_0$. *Let $\widehat{A}$ and $\widehat{B}$ be separable Banach spaces. Let $\langle F_n : n \in \mathbb{N}\rangle$ be a sequence of (codes for) bounded linear operators $F_n: \widehat{A} \to \widehat{B}$. Assume that for all $x \in \widehat{A}$ there exists $M$ such that $\|F_n(x)\| < M$ for all $n \in \mathbb{N}$. Then there exists $\alpha$ such that, for all $x \in \widehat{A}$ and $n \in \mathbb{N}$, $\|F_n(x)\| \leq \alpha \cdot \|x\|$.*

PROOF. We reason in $\mathsf{RCA}_0$. By lemma II.5.7 there exists a sequence of closed sets $\langle C_m : m \in \mathbb{N}\rangle$ in $\widehat{A}$ such that for all $x \in \widehat{A}$ and $m \in \mathbb{N}$, $x \in C_m$ if and only if $\|F_n(x)\| \leq m$ for all $n \in \mathbb{N}$. The hypothesis of the theorem implies $\widehat{A} = \bigcup_{m \in \mathbb{N}} C_m$. Hence by the Baire category theorem II.5.8 there exists $m \in \mathbb{N}$ such that $C_m$ includes a nonempty open set. Let $m_0$ be such an $m$ and let $a_0 \in A$ and $r_0 \in \mathbb{Q}^+$ be such that, for all $x \in \widehat{A}$, $\|x - a_0\| < r_0$ implies $x \in C_{m_0}$.

We claim that, for all $x \in \widehat{A}$ and $n \in \mathbb{N}$, $\|F_n(x)\| \leq 4m_0\|x\|/r_0$. If $x = 0$ this is trivial so assume $x \neq 0$. Then we have

$$\left\| a_0 - \left( a_0 + \frac{r_0 x}{2\|x\|} \right) \right\| = \left\| \frac{r_0 x}{2\|x\|} \right\| = \frac{r_0}{2} < r_0.$$

Thus

$$a_0 + \frac{r_0 x}{2\|x\|}$$

belongs to $C_{m_0}$, as does $a_0$, so for any $n \in \mathbb{N}$ we have

$$\begin{aligned} \frac{r_0}{2\|x\|}\|F_n(x)\| &= \left\| F_n\left( \frac{r_0 x}{2\|x\|} \right) \right\| \\ &\leq \left\| F_n\left( a_0 + \frac{r_0 x}{2\|x\|} \right) \right\| + \|F_n(a_0)\| \leq 2m_0. \end{aligned}$$

From this our claim follows immediately. Thus we have the conclusion of the theorem with

$$\alpha = \frac{4m_0}{r_0}.$$

This completes the proof. □

**Notes for §II.10.** A good reference for Banach space theory is Dunford/Schwartz [49]. The material of this section is from Brown/Simpson [27] and Brown [24]. For more on separable Banach spaces in subsystems of $Z_2$, see §§IV.2, IV.7, IV.9, and X.2.

## II.11. Conclusions

In this chapter we have defined the formal system $\mathsf{RCA}_0$ and developed a substantial part of ordinary mathematics within it. We have shown that many basic concepts concerning the real number system, complete separable metric spaces, continuous functions, mathematical logic, countable algebra, and separable Banach spaces can be adequately defined within $\mathsf{RCA}_0$. Using primitive recursion (§II.3) and $\Sigma^0_1$ induction, we have shown that some nontrivial mathematical theorems are provable in $\mathsf{RCA}_0$, including: nested interval completeness and the intermediate value property of the real line (§II.4); the Baire category theorem, paracompactness, and a version of the Tietze extension theorem for complete separable metric spaces (§§II.5–II.7); a strong version of the soundness theorem in mathematical logic (§II.8); existence of the algebraic closure of a countable field, and of the real closure of a countable ordered field (§II.9); the Banach/Steinhaus theorem (§II.10).

We conclude that $\mathsf{RCA}_0$ may be viewed as a formal version of computable or constructive mathematics.

Chapter III

# ARITHMETICAL COMPREHENSION

## III.1. The Formal System $\mathsf{ACA}_0$

The purpose of this chapter is to study a certain subsystem of second order arithmetic known as $\mathsf{ACA}_0$. The acronym ACA stands for "arithmetical comprehension axiom." The axioms of $\mathsf{ACA}_0$ assert the existence of subsets of $\mathbb{N}$ which are definable from given sets by formulas with no set quantifiers. This set existence principle is strong enough to permit a convenient development of large portions of ordinary mathematics which cannot be developed within the confines of $\mathsf{RCA}_0$.

DEFINITION III.1.1 (arithmetical formulas). Let $\varphi$ be a formula of the language $L_2$ of second order arithmetic. We say that $\varphi$ is *arithmetical* if $\varphi$ contains no set quantifiers. Note that an arithmetical formula may contain free set variables.

DEFINITION III.1.2 (definition of $\mathsf{ACA}_0$). The axioms of $\mathsf{ACA}_0$ are the basic axioms and the induction axiom (see definition I.2.4) together with comprehension axioms

$$\exists X \, \forall n \, (n \in X \leftrightarrow \varphi(n))$$

where $\varphi(n)$ is any arithmetical formula in which $X$ does not occur freely.

The following lemma will be useful in showing that arithmetical comprehension is needed in order to prove various theorems of ordinary mathematics.

LEMMA III.1.3. *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. $\Sigma^0_1$ comprehension, *i.e.*, $\exists X \, \forall n \, (n \in X \leftrightarrow \varphi(n))$ *restricted to* $\Sigma^0_1$ *formulas* $\varphi(n)$ *in which* $X$ *does not occur freely.*
3. *For all one-to-one functions* $f : \mathbb{N} \to \mathbb{N}$ *there exists a set* $X \subseteq \mathbb{N}$ *such that* $\forall n \, (n \in X \leftrightarrow \exists m \, (f(m) = n))$, *i.e.*, $X$ *is the range of* $f$.

PROOF. The implications $1 \to 2$ and $2 \to 3$ are trivial. The implication $3 \to 2$ is immediate from lemma II.3.7. It remains to prove that $2 \to 1$, i.e., $\Sigma^0_1$ comprehension implies arithmetical comprehension. Since

each arithmetical formula is equivalent to a $\Sigma^0_k$ formula for some $k \in \omega$ (definition II.1.2.), it suffices to prove that $\Sigma^0_1$ comprehension implies $\Sigma^0_k$ comprehension. We prove this by induction on $k \in \omega$. For $k \leq 1$ the assertion is trivial. Let $\varphi(n)$ be $\Sigma^0_{k+1}$, $k \geq 1$. Write $\varphi(n)$ as $\exists j\, \psi(n, j)$ where $\psi(n, j)$ is $\Pi^0_k$. By $\Sigma^0_k$ comprehension let $Y$ be the set of all $(n, j)$ such that $\neg\psi(n, j)$ holds. Then by $\Sigma^0_1$ comprehension let $X$ be the set of all $n$ such that $\exists j\, ((n, j) \notin Y)$. Clearly $n \in X$ if and only if $\exists j\, \psi(n, j)$, i.e., $\varphi(n)$. This completes the proof. □

We conclude this section with some remarks on models of $\mathsf{ACA}_0$. It is not hard to show that $\mathsf{ACA}_0$ has a minimum $\omega$-model, ARITH, consisting of all subsets of $\omega$ which are first order definable over $(\omega, +, \cdot, 0, 1, <)$. Equivalently,

$$\text{ARITH} = \{X \subseteq \omega : \exists n\, X \leq_{\text{T}} \emptyset^{(n)}\}$$

where $\leq_{\text{T}}$ denotes Turing reducibility and $\emptyset^{(n)}$ is the $n$th Turing jump of the empty set. For a proof of these results and other results about $\omega$-models of $\mathsf{ACA}_0$, see §VIII.1. For a discussion of non-$\omega$-models and conservation results related to $\mathsf{ACA}_0$, see chapter IX.

## III.2. Sequential Compactness

In this section we show that the set existence axioms of $\mathsf{ACA}_0$ are just strong enough to provide a good theory of sequential compactness and completeness. We begin with sequences of real numbers (the Bolzano/Weierstraß theorem). We then generalize to sequences of points in a compact metric space. Finally we consider sequences of continuous functions (the Ascoli lemma).

This section includes our first illustrations of the theme of Reverse Mathematics, which was mentioned in chapter I.

LEMMA III.2.1. *The following is provable in* $\mathsf{ACA}_0$. *Let* $\langle x_n : n \in \mathbb{N}\rangle$ *be a bounded sequence of real numbers. Then* $x = \limsup_n x_n$ *exists. Moreover, there exists a subsequence* $\langle x_{n_k} : k \in \mathbb{N}\rangle$, $n_0 < \cdots < n_k < \cdots$, *which converges to* $x$.

PROOF. We reason within $\mathsf{ACA}_0$. By a linear transformation we may assume that $0 \leq x_n \leq 1$ for all $n \in \mathbb{N}$. Define $f : \mathbb{N} \to \mathbb{N}$ by $f(k) =$ the largest $i < 2^k$ such that $i \cdot 2^{-k} \leq x_n \leq (i + 1) \cdot 2^{-k}$ for infinitely many $n \in \mathbb{N}$. This function $f$ exists by arithmetical comprehension. Put $x = \langle q_k : n \in \mathbb{N}\rangle$ where $q_k = f(k) \cdot 2^{-k}$. It is straightforward to verify that $x$ is a real number and that $\forall\epsilon > 0\, \exists m\, \forall n\, (m < n \to x_n \leq x + \epsilon)$ and $\forall\epsilon > 0\, \forall m\, \exists n\, (m < n \wedge |x - x_n| < \epsilon)$. In other words, $x = \limsup_n x_n$. Define the subsequence $\langle x_n : k \in \mathbb{N}\rangle$ by $n_0 = 0$, $n_{k+1} =$ least $n > n_k$ such that $|x - x_n| \leq 2^{-k}$. Clearly $x = \lim_k x_{n_k}$. This completes the proof. □

Theorem III.2.2. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *The* Bolzano/Weierstraß theorem: *Every bounded sequence of real numbers contains a convergent subsequence.*
3. *Every Cauchy sequence of real numbers is convergent.* (*A sequence* $\langle x_n : n \in \mathbb{N}\rangle$ *is called* Cauchy *if* $\forall \epsilon > 0\, \exists m\, \forall n\, (m < n \to |x_m - x_n| < \epsilon)$.)
4. *Every bounded sequence of real numbers has a least upper bound.*
5. *The* monotone convergence theorem: *Every bounded increasing sequence of real numbers is convergent.*

Proof. The implication $1 \to 2$ is lemma III.2.1, and the implications $2 \to 3$ and $3 \to 5$ are obvious since every bounded increasing sequence is Cauchy. Also $4 \to 5$ is trivial, so it remains to prove $1 \to 4$ and $5 \to 1$.

We first prove $1 \to 4$. Assume 1 and let $\langle x_n : n \in \mathbb{N}\rangle$ be a bounded sequence of real numbers. We may safely assume that $0 \le x_n \le 1$ for all $n$. Define $f : \mathbb{N} \to \mathbb{N}$ by $f(k) =$ the largest $i < 2^k$ such that $\exists n\, (i \cdot 2^{-k} \le x_n)$. This $f$ exists by arithmetical comprehension. Put $x = \langle q_k : k \in \mathbb{N}\rangle$ where $q_k = f(k) \cdot 2^{-k}$. It is straightforward to verify that $x$ is a real number and that $x = \sup_n x_n$, i.e., $\forall n\, (x_n \le x)$ and $\forall y\, (y < x \to \exists n\, (y < x_n))$.

It remains to prove $5 \to 1$. Assume 5 and let $f : \mathbb{N} \to \mathbb{N}$ be a given one-to-one function. Put $c_n = \sum_{i=0}^{n} 2^{-f(i)}$. Clearly $c_0 < c_1 < \cdots < c_n < \cdots < 2$ for all $n \in \mathbb{N}$. Hence by the monotone convergence theorem 5 we have the existence of

$$c = \lim_n c_n = \sum_{i=0}^{\infty} 2^{-f(i)}.$$

It is easy to see that, for all $k$,

$$(\exists i\, (f(i) = k)) \leftrightarrow \forall n\, (|c_n - c| < 2^{-k} \to \exists i \le n\, (f(i) = k)).$$

The left hand side of this equivalence is $\Sigma^0_1$ while the right hand side is $\Pi^0_1$. Hence by $\Delta^0_1$ comprehension (with parameters $c$ and $f$) we obtain $\exists X\, \forall k\, (k \in X \leftrightarrow \exists i\, (f(i) = k))$. We have now proved from 5 that for all one-to-one functions $f : \mathbb{N} \to \mathbb{N}$ the range of $f$ exists. Hence by lemma III.1.3 we have $\mathsf{ACA}_0$. This completes the proof of theorem III.2.2. □

Remark. The implication $2 \to 1$ above is our first illustration of Reverse Mathematics. The point here is that the Bolzano/Weierstraß theorem (an ordinary mathematical statement) implies arithmetical comprehension (a set existence axiom). Thus no set existence axiom weaker than arithmetical comprehension will suffice to prove the Bolzano/Weierstraß theorem. See also the discussion in §I.9.

We shall now generalize part of the previous theorem to the context of complete separable metric spaces (as defined in §II.5).

DEFINITION III.2.3 (compactness). The following definition is made in $\mathsf{RCA}_0$. A *compact metric space* is a complete separable metric space $\widehat{A}$ such that there exists an infinite sequence of finite sequences

$$\langle \langle x_{ij} : i \leq n_j \rangle : j \in \mathbb{N} \rangle, \qquad x_{ij} \in \widehat{A},$$

such that for all $z \in \widehat{A}$ and $j \in \mathbb{N}$ there exists $i \leq n_j$ such that $d(x_{ij}, z) < 2^{-j}$.

EXAMPLE III.2.4. The sequence $\langle \langle i \cdot 2^{-j} : i \leq 2^j \rangle : j \in \mathbb{N} \rangle$ shows that the closed unit interval $[0,1] = \{x : 0 \leq x \leq 1\}$ is compact. More generally, any closed bounded interval in $\mathbb{R}$ is compact. These facts are provable in $\mathsf{RCA}_0$.

LEMMA III.2.5 (compact product spaces). *The following is provable in* $\mathsf{RCA}_0$. *Let* $\widehat{A}_k$, $k \in \mathbb{N}$, *be a countably infinite sequence of compact metric spaces. Assume that there exists a doubly infinite sequence of finite sequences*

$$\langle \langle x_{ijk} : i \leq n_{jk} \rangle : j,k \in \mathbb{N} \rangle, \qquad x_{ijk} \in \widehat{A}_k,$$

*such that for all* $j,k \in \mathbb{N}$ *and* $x \in \widehat{A}_k$ *there exists* $i \leq n_{jk}$ *such that* $d(x_{ijk}, x) \leq 2^{-j}$. *Then the infinite product space* $\widehat{A} = \prod_{k \in \mathbb{N}} \widehat{A}_k$ *is compact. A similar statement holds for finite products.*

PROOF. We first consider the case of a finite product $\widehat{A} = \prod_{i=1}^{m} \widehat{A}_k$. In this case, for each $j \in \mathbb{N}$, let $l_j =$ the smallest $l$ such that $m \cdot 2^{-l} \leq 2^{-j}$. Put $n_j = \prod_{k=1}^{m} (n_{l_j k} + 1) - 1$ and let $\langle x_{ij} : i \leq n_j \rangle$ be an enumeration of $\prod_{k=1}^{m} \{x_{il_jk} : i \leq n_{l_jk}\}$. Then $\langle \langle x_{ij} : i \leq n_j \rangle : j \in \mathbb{N} \rangle$ attests to the compactness of $\widehat{A}$.

In the case of a countably infinite product $\widehat{A} = \prod_{k \in \mathbb{N}} \widehat{A}_k$, for each $j \in \mathbb{N}$ let $l_j =$ smallest $l$ such that $(j+2) \cdot 2^{-l} \leq 2^{-j-1}$. Put $n_j = \prod_{k=0}^{j+1} (n_{l_j k} + 1) - 1$ and let $\langle x_{ij} : i \leq n_j \rangle$ be an enumeration of $\prod_{k=0}^{j+1} \{x_{il_jk} : i \leq n_{l_jk}\}$. Again $\langle \langle x_{ij} : i \leq n_j \rangle : j \in \mathbb{N} \rangle$ attests to the compactness of $\widehat{A}$. This completes the proof of the lemma. □

EXAMPLES III.2.6. Within $\mathsf{RCA}_0$, we have:

1. Any closed bounded rectangle in $\mathbb{R}^m$ is compact.
2. The Cantor space $2^{\mathbb{N}} = \{0,1\}^{\mathbb{N}}$ is compact.
3. The Hilbert cube $[0,1]^{\mathbb{N}}$ is compact.
4. For any compact metric space $\widehat{A}$, the infinite product space $\widehat{A}^{\mathbb{N}} = \prod_{k \in \mathbb{N}} \widehat{A}$ is compact.

Our generalization of theorem III.2.2 to complete separable metric spaces is as follows.

Theorem III.2.7. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *In any compact metric space, every sequence of points has a convergent subsequence.*
3. *In any complete separable metric space, every Cauchy sequence is convergent.* (*A sequence* $\langle x_n : n \in \mathbb{N}\rangle$, $x_n \in \widehat{A}$, *is said to be* Cauchy *if* $\forall \epsilon > 0\, \exists m\, \forall n\, (m < n \to d(x_m, x_n) \leq \epsilon)$.)

Proof. The proof of $1 \to 2$ is a straightforward generalization of the proof of lemma III.2.1. The proof of $1 \to 3$ is left as an exercise for the reader. (Compare exercise II.5.2.) The implications $2 \to 1$ and $3 \to 1$ are immediate from theorem III.2.2 since 2 and 3 are generalizations of III.2.2.2 and III.2.2.3 respectively. □

We end this section by showing that $\mathsf{ACA}_0$ is just strong enough to prove the Ascoli lemma for compact metric spaces. First we give the relevant definitions. Let $\widehat{A}$ and $\widehat{B}$ be complete separable metric spaces. Let $f_n : \widehat{A} \to \widehat{B}$, $n \in \mathbb{N}$, be a sequence of continuous functions. The sequence is said to be *equicontinuous* if for all $\epsilon > 0$ there exists $\delta > 0$ such that, for all $x, x' \in \widehat{A}$, $d(x, x') < \delta$ implies $d(f_n(x), f_n(x')) \leq \epsilon$ for all $n \in \mathbb{N}$. The sequence is said to be *uniformly convergent* if there exists a continuous function $f : \widehat{A} \to \widehat{B}$ such that for all $\epsilon > 0$ there exists $m$ such that for all $n > m$ and $x \in \widehat{A}$, $d(f_n(x), f(x)) < \epsilon$.

Theorem III.2.8 (Ascoli lemma). *The following is provable in* $\mathsf{ACA}_0$. *Let* $\widehat{A}$ *and* $\widehat{B}$ *be compact metric spaces. Let* $\langle f_n : n \in \mathbb{N}\rangle$ *be an equicontinuous sequence of continuous functions* $f_n : \widehat{A} \to \widehat{B}$. *Then there exists a uniformly convergent subsequence* $\langle f_{n_k} : k \in \mathbb{N}\rangle$, $n_0 < n_1 < \cdots < n_k < \cdots$.

Proof. We reason in $\mathsf{ACA}_0$. Since $\widehat{A}$ is compact, let

$$\langle \langle x_{ij} : i \leq n_j \rangle : j \in \mathbb{N}\rangle, \qquad x_{ij} \in \widehat{A},$$

be as in III.2.3. Let $I$ be the set of all $(i, j) \in \mathbb{N} \times \mathbb{N}$ such that $i \leq n_j$. For each $m \in \mathbb{N}$ put $z_m = \langle f_m(x_{ij}) : (i, j) \in I\rangle$. Thus $\langle z_m : n \in \mathbb{N}\rangle$ is a sequence of points in the infinite product space $\widehat{B}^I$. By III.2.6.4 this space is compact. Hence by III.2.7 there exists a convergent subsequence $\langle z_{m_k} : k \in \mathbb{N}\rangle$. It follows that $\langle f_{m_k}(x_{ij}) : k \in \mathbb{N}\rangle$ is convergent for each $(i, j) \in I$. Using arithmetical comprehension as in the last part of the proof of III.2.1, we may if necessary refine our subsequence so that

$$\forall i\, \forall j\, \forall k\, ((i \leq n_j \wedge j \leq k) \to d(f_{m_k}(x_{ij}), f_{m_{k+1}}(x_{ij})) \leq 2^{-k-1}).$$

By yet another application of arithmetical comprehension, define $h : \mathbb{N} \to \mathbb{N}$ by $h(l) =$ smallest $n$ such that $d(a, a') < 2^{-n}$ implies $d(f_m(a), f_m(a')) \leq 2^{-l}$ for all $m \in \mathbb{N}$ and $a, a' \in A$. It follows that $h$ is a *modulus of*

*equicontinuity*, i.e., $d(x,x') < 2^{-h(l)}$ implies $d(f_m(x), f_m(x')) \leq 2^{-l}$ for all $l, m \in \mathbb{N}$ and $x, x' \in \widehat{A}$.

Define a code $F$ for a continuous function $f$ from $\widehat{A}$ to $\widehat{B}$ by putting $(a,r)F(b,s)$ if and only if $a \in A$, $r \in \mathbb{Q}^+$, $b \in B$, $s \in \mathbb{Q}^+$, and there exist $i, j, k$ and $l$ such that $i \leq n_j$, $(a,r) < (x_{ij}, 2^{-j})$, $h(l) \leq j \leq k$, $l \leq k$, and $(f_{m_k}(x_{ij}), 2^{-l+1}) < (b,s)$. It is straightforward to check that $f$ is totally defined on $\widehat{A}$, that

$$\forall i\, \forall j\, \forall k\, ((i \leq n_j \wedge j \leq k) \rightarrow d(f_{m_k}(x_{ij}), f(x_{ij})) \leq 2^{-k}),$$

and that $d(x,x') < 2^{-h(l)}$ implies $d(f(x), f(x')) \leq 2^{-l}$ for all $l \in \mathbb{N}$ and $x, x' \in \widehat{A}$. From these facts it follows that $d(f_m(x), f(x)) \leq 3 \cdot 2^{-l}$ for all $l \in \mathbb{N}$ and $k \geq \max(l, h(l))$. Thus $\langle f_{m_k} : k \in \mathbb{N} \rangle$ converges uniformly to $f$. This proves the theorem. □

As another instance of Reverse Mathematics, we have:

THEOREM III.2.9. *The following are pairwise equivalent over* $\mathsf{RCA}_0$:

1. *arithmetical comprehension*;
2. *the Ascoli lemma*;
3. *The Bolzano/Weierstraß theorem*.

PROOF. The Bolzano/Weierstraß theorem is the special case of the Ascoli lemma in which $\widehat{A}$ and $\widehat{B}$ are closed bounded intervals and the $f_n$'s are constant functions. This proves $2 \rightarrow 3$. The implications $1 \rightarrow 2$ and $3 \rightarrow 1$ have already been proved in III.2.8 and III.2.2 respectively. □

**Notes for §III.2.** Theorem III.2.2 was stated without proof by Friedman [69]. The definition of compact metric spaces within $\mathsf{RCA}_0$, as well as lemma III.2.5 and the examples in III.2.6, are due to Brown/Simpson [24, 27, 28]. For more on compact metric spaces, see §§IV.1 and IV.2 below. Theorems III.2.8 and III.2.9 are due to Simpson, previously unpublished. For a somewhat different treatment of the Ascoli lemma within $\mathsf{ACA}_0$, see Simpson [236].

## III.3. Strong Algebraic Closure

We saw in §II.9 that $\mathsf{RCA}_0$ proves that every countable field has an algebraic closure. One might ask whether $\mathsf{RCA}_0$ proves the stronger statement that every countable field is isomorphic to a subfield of its algebraic closure. We now show that $\mathsf{ACA}_0$ is needed to prove this stronger statement.

DEFINITION III.3.1 (strong algebraic closure). The following definitions are made in $\mathsf{RCA}_0$. Let $K$ be a countable field. A *strong algebraic closure* of $K$ is an algebraic closure $h : K \rightarrow \widetilde{K}$ (see definition II.9.2) with the further property that $h$ is an isomorphism of $K$ onto a subfield of $\widetilde{K}$.

The notion of *strong real closure* is defined similarly (compare definition II.9.5).

Theorem III.3.2. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *Every countable field has a strong algebraic closure.*
3. *Every countable field is isomorphic to a subfield of a countable algebraically closed field.*
4. *Every countable ordered field has a strong real closure.*
5. *Every countable ordered field is isomorphic to a subfield of a countable real closed ordered field.*

Proof. First assume $\mathsf{ACA}_0$ and let $K$ be a countable field. By theorem II.9.4 let $h\colon K \to \widetilde{K}$ be an algebraic closure of $K$. By $\Sigma^0_1$ comprehension let $L$ be the set of all $b \in \widetilde{K}$ such that $\exists a\,(h(a) = b)$. Then $L$ is a subfield of $\widetilde{K}$ and $h$ is an isomorphism of $K$ onto $L$. Hence $h\colon K \to \widetilde{K}$ is a strong algebraic closure of $K$. This proves that 1 implies 2.

The implication from 2 to 3 is trivial. We shall now prove that 3 implies 1. We reason in $\mathsf{RCA}_0$. Assume 3. Instead of proving $\mathsf{ACA}_0$ we shall prove the equivalent statement III.1.3.3. Let $f\colon \mathbb{N} \to \mathbb{N}$ be given. By theorem II.9.7 let $\overline{\mathbb{Q}}$ be the real closure of $\mathbb{Q}$. Let $\langle p_j : j \in \mathbb{N}\rangle$ be the enumeration of the rational primes in increasing order, i.e., $p_0 = 2$, $p_1 = 3$, $p_2 = 5$, $\ldots$. For each $n \in \mathbb{N}$ let $K_n$ be the subfield of $\overline{\mathbb{Q}}$ generated by $\{\sqrt{p_{f(i)}} : i < n\}$. Because we lack $\Sigma^0_1$ comprehension, we cannot form the subfield $\bigcup_{n\in\mathbb{N}} K_n$. However, we can apply lemma II.3.7 to find a field $K$ and a monomorphism $g\colon K \to \overline{\mathbb{Q}}$ such that $\forall b\,(\exists n\,(b \in K_n) \leftrightarrow \exists a\,(g(a) = b))$. Intuitively, $K = \mathbb{Q}(\{\sqrt{p_{f(i)}} : i \in \mathbb{N}\})$. Now by 3 let $h\colon K \to L \subseteq M$ be an isomorphism of $K$ onto a subfield $L$ of a countable algebraically closed field $M$. Then for all $j \in \mathbb{N}$ we have $\exists i\,(f(i) = j)$ if and only if $\forall b\,((b \in M \wedge b^2 = p_j) \to b \in L)$. It follows by $\Delta^0_1$ comprehension that $\exists X\,\forall j\,(j \in X \leftrightarrow \exists i\,(f(i) = j))$. By lemma III.1.3 this implies $\mathsf{ACA}_0$.

We have now established the pairwise equivalence of 1, 2, and 3. An obvious modification establishes the pairwise equivalence of 1, 4, and 5. This completes the proof of theorem III.3.2. □

Remark III.3.3 (formally real fields). Theorem III.3.2 remains true if the ordered fields are replaced by formally real fields. Again the same proof applies. For more on formally real fields see §IV.4.

**Notes for §III.3.** Theorem III.3.2 is from Friedman/Simpson/Smith [78]. The idea of the proof goes back to Fröhlich/Shepherdson [82].

## III.4. Countable Vector Spaces

In this section we shall show that $\mathsf{ACA}_0$ is just strong enough to prove that every countable vector space has a basis. We shall also obtain some strengthenings of this result.

DEFINITION III.4.1 (countable vector spaces). The following definitions are made in $\mathsf{RCA}_0$. Let $K$ be a countable field (as defined in §II.9). A *countable vector space* $V$ over $K$ consists of a countable Abelian group $|V|, +_V, -_V, 0_V$ (see definition III.6.1 below) together with a function $\cdot_V : |K| \times |V| \to |V|$ which obeys the usual axioms for scalar multiplication, e.g., $a \cdot (u + v) = a \cdot u + a \cdot v$. For notational convenience we shall sometimes write $|V|$ as $V$.

A *basis* of $V$ over $K$ is a set $E \subseteq |V|$ such that each $v \in V$ can be expressed uniquely in the form $v = \sum_{e \in E_0} a_e \cdot e$ where $E_0$ is a finite subset of $E$ and, for each $e \in E_0$, $0 \neq a_e \in K$.

LEMMA III.4.2. $\mathsf{ACA}_0$ *proves that every countable vector space over a countable field has a basis.*

PROOF. We reason in $\mathsf{ACA}_0$. Let $V$ be a countable vector space over a countable field $K$. By arithmetical comprehension, there exists a set $S$ consisting of all finite sequences $\langle v_0, \dots, v_{n-1}, v_n \rangle$, $n \in \mathbb{N}$, such that $v_n = \sum_{i<n} a_i \cdot v_i$ for some $a_0, \dots, a_{n-1} \in K$. Using $S$ as a parameter, we can apply primitive recursion (§II.3) to define a sequence of vectors $e_0, e_1, \dots, e_n, \dots$ where $e_n =$ the least $v \in V$ such that $\langle e_0, \dots, e_{n-1}, v \rangle \notin S$. (The recursion may end after finitely many steps.) Here $V = |V| \subseteq \mathbb{N}$ and "least" refers to the usual ordering of $\mathbb{N}$. The set $E = \{e_0, e_1, \dots\}$ is easily shown to be a basis for $V$. This proves the lemma. □

THEOREM III.4.3. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *Every countable vector space over a countable field has a basis.*
3. *Every countable vector space over the rational field* $\mathbb{Q}$ *has a basis.*

PROOF. Lemma III.4.2 gives the implication $1 \to 2$, and 2 implies 3 trivially. It remains to prove $3 \to 1$.

We reason within $\mathsf{RCA}_0$. Assume 3. Our goal is to prove arithmetical comprehension. Let $f : \mathbb{N} \to \mathbb{N}$ be a one-to-one function. By lemma III.1.3, it suffices to prove that the range of $f$ exists.

Let $V_0$ be the set of formal sums $\sum_{i \in I} q_i \cdot x_i$ where $I \subseteq \mathbb{N}$, $I$ is finite, and $0 \neq q_i \in \mathbb{Q}$. Thus $V_0$ is a vector space over $\mathbb{Q}$ and $X = \{x_n : n \in \mathbb{N}\}$ is a basis of $V_0$. For each $m \in \mathbb{N}$ put

$$x'_m = x_{2f(m)} + m \cdot x_{2f(m)+1}$$

and let $U$ be the subspace of $V_0$ generated by $X' = \{x'_m : m \in \mathbb{N}\}$. $U$ exists by $\Delta^0_1$ comprehension since $\sum_{i \in I} q_i \cdot x_i$ belongs to $U$ if and only if

$\forall n\,(q_{2n} \neq 0 \to f(q_{2n+1}/q_{2n}) = n)$ and $\forall n\,(q_{2n} = 0 \to q_{2n+1} = 0)$. Note that $X'$ is a basis of $U$.

Since $U$ is a subspace of $V_0$, we may form the quotient space $V = V_0/U$ as follows. The elements of $V$ are those $v \in V_0$ such that $\forall w\,((w < v \wedge w \in V_0) \to v - w \notin U)$, i.e., $v$ is the minimal representative of an equivalence class under the equivalence relation $v - w \in U$. The vector space operations on $V$ are defined accordingly. For instance, for all $u, v \in V$ we put $u +_V v =$ the unique $w \in V$ such that $w$ is equivalent to $u +_{V_0} v$ under the mentioned equivalence relation. Thus $V$ is a vector space over $\mathbb{Q}$.

By our assumption 3, $V = V_0/U$ has a basis, call it $X''$. It follows that $X' \cup X''$ is a basis of $V_0$. Now for any $n \in \mathbb{N}$, we have $\exists m\,(f(m) = n)$ if and only if at least one of the unique expressions for $x_{2n}$ and $x_{2n+1}$ in terms of the basis $X' \cup X''$ involves an element $x'_m$ from $X'$ such that $f(m) = n$. Hence, by $\Delta^0_1$ comprehension, the range of $f$ exists.

This completes the proof of theorem III.4.3. □

Remark. The point of the above theorem is that a fairly innocuous looking mathematical assertion ("every countable vector space over $\mathbb{Q}$ has a basis") is in fact equivalent to arithmetical comprehension. This is an instance of Reverse Mathematics. We shall now strengthen the theorem by showing that an even weaker looking assertion ("every countable vector space over $\mathbb{Q}$ either is finite dimensional or contains an infinite linearly independent set") is also equivalent to arithmetical comprehension.

A countable vector space $V$ over $K$ is said to be *finite dimensional* if it has a finite basis. A set $Y \subseteq |V|$ is said to be *linearly independent* if there is no equation $\sum_{i=0}^{k} a_i \cdot y_i = 0$ where $0 \neq a_i \in K$ and $y_0, \ldots, y_k$ are distinct elements of $Y$.

Theorem III.4.4. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *Every countable vector space (over* $\mathbb{Q}$*) has a basis.*
3. *Every countable vector space over* $\mathbb{Q}$ *either is finite dimensional or contains an infinite linearly independent set.* (*Instead of the rational field* $\mathbb{Q}$ *we could use any infinite countable field.*)

Proof. Lemma III.4.2 gives the implication from 1 to 2, and 2 implies 3 trivially. It remains to prove that 3 implies 1. We reason in $\mathsf{RCA}_0$.

As in the proof of theorem III.4.3, let $V_0$ be an infinite dimensional vector space over $\mathbb{Q}$ which has a basis. For any finite set of vectors $v_0, \ldots, v_{n-1} \in V_0$, let $(v_0, \ldots, v_{n-1})$ be the set of $v \in V_0$ such that $v = \sum_{i<n} q_i \cdot v_i$ for some $q_0, \ldots, q_{n-1} \in \mathbb{Q}$. Note that, for $V_0$, the set $S$ of finite sequences $\langle v_0, \ldots, v_{n-1}, v_n \rangle$ such that $v_n \in (v_0, \ldots, v_{n-1})$ exists in $\mathsf{RCA}_0$

since we can use the basis plus determinants to test for linear independence of finite sets. Hence we can proceed as in the proof of lemma III.4.2 to define a sequence of vectors $e_n = \text{least } v \in V_0 \text{ such that } v \notin (e_0, \ldots, e_{n-1})$. Note that $m < n$ implies $e_m < e_n$. Hence by $\Delta^0_1$ comprehension the set of all $e_n$, $n \in \mathbb{N}$, exists and is therefore a basis of $V_0$.

Assume 3. As in the proof of theorem III.4.3, let $f : \mathbb{N} \to \mathbb{N}$ be a one-to-one function. We want to show that the range of $f$ exists. Let us say that $m \in \mathbb{N}$ is *true* if $f(n) > f(m)$ for all $n > m$ and *false* otherwise. We may safely assume that 0 is false. Since the property of being false is $\Sigma^0_1$, lemma II.3.7 provides a one-to-one function $g : \mathbb{N} \to \mathbb{N}$ such that $\forall m\,(m \text{ is false} \leftrightarrow \exists k\,(g(k) = m))$. We may safely assume that $g(0) = 0$, hence $g(k) > 0$ for all $k > 0$.

By primitive recursion define vectors $u_k = e_0 + a_k \cdot e_{g(k)}$, $k > 0$, where the scalar $a_k \in \mathbb{Q}$, $a_k \neq 0$ is chosen so that for all vectors $v \leq k$, if $v \notin (u_1, \ldots, u_{k-1})$ then $v \notin (u_1, \ldots, u_{k-1}, u_k)$. To see that such $a_k$ exists, note that since $e_0, e_{g(1)}, \ldots, e_{g(k-1)}, e_{g(k)}$ are linearly independent, so are $e_0, u_1, \ldots, u_{k-1}, e_{g(k)}$. Hence for any $v \notin (u_1, \ldots, u_{k-1})$ there is at most one scalar $b_v \in \mathbb{Q}$ such that $v \in (u_1, \ldots, u_{k-1}, e_0 + b_v \cdot e_{g(k)})$. Thus we need only choose $a_k$ outside the finite set $\{0\} \cup \{b_v : v \in |V_0| \wedge v \leq k\}$. Now let $U$ be the subspace of $V_0$ generated by $\{u_k : k > 0\}$. Here $U$ exists by $\Delta^0_1$ comprehension since $v \in U$ if and only if $v \in (u_1, \ldots, u_v)$.

$U$ is a subspace of $V_0$ so, as in the proof of theorem III.4.3, we may form the quotient space $V = V_0/U$. Since the $e_m$'s for all true $m \in \mathbb{N}$ are linearly independent modulo $U$, we see that $V$ is not finite dimensional. Hence by our assumption 3 there exists an infinite linearly independent set $Y \subseteq V$. Viewing $Y$ as a subset of $V_0$, we see that $Y$ is linearly independent modulo the subspace $U$. In particular, there is at most one way to express $e_0$ as an element of $U$ plus a linear combination of elements of $Y$. Since $e_0 \notin U$, the linear combination of elements of $Y$ must be nontrivial. Hence by deleting at most one element from $Y$, we may assume that $Y$ is linearly independent modulo $\{e_0\} \cup U$. Hence $Y$ is linearly independent modulo all the $e_{g(k)}$, $k \in \mathbb{N}$, i.e., all the $e_m$ such that $m$ is false.

Let $\langle y_j : j \in \mathbb{N}\rangle$ be the enumeration of the elements of $Y$ in increasing order (lemma II.3.6). We claim that for each $j$, the number of true $m$ with $e_m < y_j$ is at least $j$. To see this, suppose not and let $n$ be the least integer such that $e_n \geq y_j$. Then the dimension of $(e_0, \ldots, e_{n-1})$ modulo the $e_m$ with $m$ false is less than $j$. But the dimension of $(y_0, \ldots y_{j-1})$ modulo the $e_m$ with $m$ false is $j$. Hence there is at least one $i < j$ such that $y_i \notin (e_0, \ldots, e_{n-1})$. Hence $y_i \geq e_n$ since we defined $e_n = \text{least } v \text{ such that } v \notin (e_0, \ldots, e_{n-1})$. Hence $e_n \leq y_i < y_j$, a contradiction.

From the previous claim it follows that if $e_m \geq y_j$ then $f(m) \geq j$. Hence for all $j$ we have $\exists m\,(f(m) = j)$ if and only if $\exists m\,(e_m < y_{j+1} \wedge f(m) = j)$. Hence by $\Delta^0_1$ comprehension the set of all $j$ such that

$\exists m\,(f(m) = j)$ exists. This gives $\mathsf{ACA}_0$ in view of lemma III.1.3. The proof of theorem III.4.4 is complete. □

We end this section by mentioning a result on algebraic independence which is analogous to theorem III.4.3 on linear independence.

DEFINITION III.4.5 (algebraic independence). The following definitions are made in $\mathsf{RCA}_0$. Let $K$ and $L$ be countable fields with $K \subseteq L$. A set $Y \subseteq L$ is said to be *algebraically independent over* $K$ if there is no non-trivial polynomial equation $f(b_1, \ldots, b_k) = 0$, $b_i \in Y$, $f(x_1, \ldots, x_k) \in K[x_1, \ldots, x_k]$. A *transcendence base* for $L$ over $K$ is a maximal algebraically independent set.

THEOREM III.4.6. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *For every pair of countable fields* $K \subseteq L$ *there exists a transcendence base for* $L$ *over* $K$.
3. *Let* $L$ *be any countable field of characteristic zero with no finite transcendence base. Then* $L$ *contains an infinite algebraically independent set*.

PROOF. The ideas underlying the proof are the same as for theorem III.4.4. For details see Friedman/Simpson/Smith [78]. □

**Notes for §III.4.** The results of this section are due to Friedman/Simpson/Smith [78]. The ideas in the proof of theorem III.4.4 are closely related to ideas of Dekker (see Rogers [208, §9.5]) and Metakides/Nerode [187]. In the recursion-theoretic Metakides/Nerode setting, the proof of theorem III.4.4 would amount to constructing a recursive, infinite dimensional vector space $V$ over $\mathbb{Q}$ such that the complete recursively enumerable set is Turing reducible to any infinite linearly independent subset of $V$. Metakides/Nerode [187] contains a result which is somewhat weaker than this. (In the same recursion-theoretic setting, the proof of theorem III.4.3 would amount to constructing a recursive vector space $V$ over $\mathbb{Q}$ such that the complete recursively enumerable set is Turing reducible to any basis of $V$.)

The proof of theorem III.4.6 is obtained by combining the proof of theorem III.4.4 with methods of Fröhlich/Shepherdson [82]. For details see Friedman/Simpson/Smith [78].

## III.5. Maximal Ideals in Countable Commutative Rings

In this section we show that the axioms of $\mathsf{ACA}_0$ are just strong enough to prove that every countable commutative ring has a maximal ideal. Prime ideals will be considered in §IV.6.

DEFINITION III.5.1 (countable commutative rings). The following definitions are made in $\mathsf{RCA}_0$. A *countable commutative ring* $R$ consists of a set $|R| \subseteq \mathbb{N}$ together with binary operations $+_R, \cdot_R : |R| \times |R| \to |R|$ and a unary operation $-_R : |R| \to |R|$ and distinguished elements $0_R, 1_R \in |R|$ satisfying the usual commutative ring axioms, including $\forall x \, \forall y \, (x \cdot y = y \cdot x)$ and $0 \neq 1$. For notational convenience we write $|R|$ as $R$. A *countable integral domain* is a countable commutative ring $R$ satisfying $\forall x \, \forall y \, (x \cdot y = 0 \to (x = 0 \vee y = 0))$.

DEFINITION III.5.2 (ideals). The following definitions are made in $\mathsf{RCA}_0$. Let $R$ be a countable commutative ring. An *ideal* of $R$ is a set $I \subseteq R$ such that $0 \in I$ and $1 \notin I$ and $\forall a \, \forall b \, ((a \in I \wedge b \in I) \to a + b \in I)$ and $\forall r \, \forall a \, ((r \in R \wedge a \in I) \to r \cdot a \in I)$. Given an ideal $I$ we can form the *quotient ring* $R/I$. The elements of $R/I$ are defined to be just those $r \in R$ such that $\forall s \, ((s < r \wedge s \in R) \to r - s \notin I))$, i.e., minimal elements of equivalence classes under the equivalence relation $r - s \in I$. Ring operations on $R/I$ are defined accordingly.

DEFINITION III.5.3 (prime and maximal ideals). The following definitions are made in $\mathsf{RCA}_0$. Let $R$ be a countable commutative ring. A *prime ideal* of $R$ is an ideal $P$ such that $\forall r \, \forall s \, ((r \in R \wedge s \in R \wedge r \cdot s \in P) \to (r \in P \vee s \in P))$. This is equivalent to saying that $R/P$ is an integral domain. A *maximal ideal* of $R$ is an ideal $M$ such that $\forall r \, ((r \in R \wedge r \notin M) \to \exists s \, (s \in R \wedge r \cdot s - 1 \in M))$. This is equivalent to saying that $R/M$ is a field. Obviously every maximal ideal is prime.

LEMMA III.5.4. $\mathsf{ACA}_0$ *proves that every countable commutative ring has a maximal ideal.*

PROOF. We reason in $\mathsf{ACA}_0$. For any $X \subseteq R$ say that $X$ is *good* if $X$ does not generate $R$ as an $R$-module, i.e., 1 is not of the form $\sum_{i=1}^{n} s_i \cdot a_i$ where $s_i \in R$, $a_i \in X$. Let $\langle r_n : n \in \mathbb{N} \rangle$ be an enumeration of the elements of $R$. Define $f : \mathbb{N} \to \{0, 1\}$ by $f(n) = 0$ if $\{r_m : m < n \wedge f(m) = 0\} \cup \{r_n\}$ is good, $f(n) = 1$ otherwise. Let $M$ be the set of all $r_m$ such that $f(m) = 0$. Clearly $M$ is a maximal ideal of $R$. □

THEOREM III.5.5. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *Every countable commutative ring has a maximal ideal.*
3. *Every countable integral domain has a maximal ideal.*

PROOF. Lemma III.5.4 gives the implication from 1 to 2, and the implication from 2 to 3 is trivial. It remains to prove that 3 implies 1.

Assume 3. Instead of proving $\mathsf{ACA}_0$ we shall prove the equivalent statement III.1.3.3. Let $f : \mathbb{N} \to \mathbb{N}$ be given. We want to construct a countable integral domain $R$ which, in a suitable sense, encodes the range of $f$. We proceed as follows. Let $R_0 = \mathbb{Q}[\langle x_n : n \in \mathbb{N} \rangle]$ be the polynomial

ring over the rational field $\mathbb{Q}$ with countably many indeterminates. Let $K_0 = \mathbb{Q}(\langle x_n : n \in \mathbb{N}\rangle)$ be the field of fractions of $R_0$, i.e., $K_0$ is the field consisting of all fractions $r/s$ where $r \in R_0$, $s \in R_0$, $s \neq 0$. Let $\varphi(b)$ be a $\Sigma^0_1$ formula asserting that $b \in K_0$ and $b$ is of the form $r/s$ where $r \in R_0$, $s \in R_0$, and $s$ contains at least one monomial of the form $qx^{e_1}_{f(m_1)}x^{e_2}_{f(m_2)} \cdots x^{e_k}_{f(m_k)}$ with $q \in \mathbb{Q}$, $q \neq 0$, $k \geq 0$. By lemma II.3.7 let $R$ be a countable integral domain and $h : R \to K_0$ a monomorphism such that $\forall b\,(\varphi(b) \leftrightarrow \exists a\,(h(a) = b))$. By 3 let $M$ be a maximal ideal of $R$.

We claim that, for all $n \in \mathbb{N}$, $\exists m\,(f(m) = n)$ if and only if $h^{-1}(x_n) \notin M$. If $n = f(m)$ then $\varphi(1/x_n)$ holds, hence $h^{-1}(x_n)$ has an inverse $h^{-1}(1/x_n)$ in $R$, hence $h^{-1}(x_n) \notin M$ since $M$ is an ideal of $R$. Conversely, if $h^{-1}(x_n) \notin M$, let $a \in R$ and $b \in M$ be such that $a \cdot h^{-1}(x_n) - 1 = b$. Put $h(b) = r/s$ where $r \in R_0$, $s \in R_0$, $s \neq 0$. Since $b \in M$ it follows that $b$ is not invertible in $R$, hence $r$ cannot contain any monomial of the form $qx^{e_1}_{f(m_1)}x^{e_2}_{f(m_2)} \cdots x^{e_k}_{f(m_k)}$, while of course $s$ does contain at least one such monomial. But $h(a) \cdot x_n - 1 = h(b) = r/s$, hence $h(a) \cdot x_n \cdot s = r + s$. We conclude that $n = f(m)$ for some $m$. This proves our claim.

By $\Delta^0_1$ comprehension let $X$ be the set of of all $n$ such that $h^{-1}(x_n) \notin M$. Then $\forall n\,(n \in X \leftrightarrow \exists m\,(f(m) = n))$. This gives $\mathsf{ACA}_0$ in view of lemma III.1.3. The proof of theorem III.5.5 is complete. □

Remark III.5.6 (localization). Roughly speaking, the idea of the above proof is that $R = R_0(R_0 \setminus P)^{-1}$ where $P$ is a (carefully chosen) prime ideal of $R_0$. One describes this situation by saying that $R$ is the *local ring* obtained from $R_0$ by *localizing* at the prime ideal $P$. It follows that $R$ has a unique maximal ideal $M$, namely $M = P(R_0 \setminus P)^{-1}$. The prime ideal $P$ is taken to be generated by the indeterminates $x_n$ such that $n \notin$ range of $f$. Thus $x_n \in M$ if and only if $n \notin$ range of $f$.

Remark III.5.7. Theorem III.5.5 provides yet another illustration of Reverse Mathematics. Namely, $\mathsf{ACA}_0$ is both necessary and sufficient to prove the existence of maximal ideals in countable commutative rings. In §IV.6 we shall obtain an analogous result with maximal ideals replaced by prime ideals, and $\mathsf{ACA}_0$ replaced by $\mathsf{WKL}_0$.

Remark III.5.8. Hatzikiriakou [108, 109] has shown that $\mathsf{ACA}_0$ is equivalent over $\mathsf{RCA}_0$ to the assertion that every countable commutative ring has a *minimal* prime ideal.

**Notes for §III.5.** The main results of this section are from Friedman/Simpson/Smith [78]. For general information about local rings and localization, see any textbook of commutative algebra, e.g., Zariski/Samuel [282, §IV.11].

## III.6. Countable Abelian Groups

In this section we show that the axioms of $\mathsf{ACA}_0$ are just strong enough to prove several basic results in the theory of countable Abelian groups. Later, in §§V.7 and VI.4, we shall return to this topic and show that the deeper theory of countable Abelian groups requires set existence axioms which are stronger than those of $\mathsf{ACA}_0$.

We begin by discussing torsion subgroups.

DEFINITION III.6.1 (countable Abelian groups). The following definitions are made in $\mathsf{RCA}_0$. A *countable Abelian group* $A$ consists of a set $|A| \subseteq \mathbb{N}$ together with a binary operation $+_A : |A| \times |A| \to A$ and a unary operation $-_A : |A| \to |A|$ and a distinguished element $0_A \in |A|$ such that the system $|A|, +_A, -_A, 0_A$ obeys the usual Abelian group axioms, e.g., $\forall x\,(x + (-x) = 0)$ and $\forall x\,\forall y\,(x + y = y + x)$. For notational convenience we write $|A|$ as $A$. By primitive recursion define $f : \mathbb{N} \times A \to A$ by $f(0, a) = 0$, $f(n + 1, a) = f(n, a) + a$, and put $na = f(n, a)$. Thus $na = a + \cdots + a$ where the summation is repeated $n$ times. A *torsion element* of A is an element $a \in A$ such that $\exists n\,(n \geq 1 \wedge na = 0)$.

THEOREM III.6.2 (torsion subgroup). $\mathsf{ACA}_0$ *is equivalent over* $\mathsf{RCA}_0$ *to the assertion that every countable Abelian group has a subgroup consisting of the torsion elements.*

PROOF. If $A$ is a countable Abelian group, we can use arithmetical comprehension to form the set $T$ consisting of all $a \in A$ such that $\exists n\,(n \geq 1 \wedge na = 0)$. It is then easy to see that $T$ is a subgroup of $A$.

For the converse, assume that every countable Abelian group has a subgroup consisting of the torsion elements. Instead of proving $\mathsf{ACA}_0$ we shall prove the equivalent assertion III.1.3.3. Let $f : \mathbb{N} \to \mathbb{N}$ be a given one-to-one function. Form a countable Abelian group $A$ given by generators $x_i$, $i \in \mathbb{N}$, and relations $(2m + 1)x_{f(m)} = 0$, $m \in \mathbb{N}$. The elements of $A$ are finite formal sums $\sum n_i x_i$ where $n_i \in \mathbb{Z}$ and $\forall m\,(m < |n_i| \to i \neq f(m))$. This set of formal sums exists by $\Sigma^0_0$ comprehension. Now by assumption let $T$ be the subgroup of $A$ consisting of the torsion elements. By $\Delta^0_1$ comprehension let $X$ be the set of all $i$ such that $x_i \in T$. Then clearly $\forall i\,(i \in X \leftrightarrow \exists m\,(f(m) = i))$. By lemma III.1.3 this gives $\mathsf{ACA}_0$. The proof of theorem III.6.2 is complete. □

Next we turn to a discussion of divisible closures.

DEFINITION III.6.3 (divisible closure). The following definitions are made in $\mathsf{RCA}_0$. Let $D$ be a countable Abelian group. We say that $D$ is *divisible* if for all $d \in D$ and all $n \geq 1$ there exists $c \in D$ such that $nc = d$. Given a countable Abelian group $A$, a *divisible closure* of $A$ is a countable divisible Abelian group $D$ together with a monomorphism

$h\colon A \to D$ such that for all nonzero $d \in D$ there exists $n \in \mathbb{N}$ such that $nd = h(a)$ for some nonzero $a \in A$.

We shall show that the existence of divisible closures is provable in $\mathsf{RCA}_0$ but the uniqueness requires $\mathsf{ACA}_0$.

Theorem III.6.4 (existence of divisible closure). *It is provable in* $\mathsf{RCA}_0$ *that every countable Abelian group $A$ has a divisible closure.*

Proof. Let $A$ be a countable Abelian group. We may assume that $A = C/K$ where $C$ is a countable free Abelian group and $K$ is a subgroup of $C$. Since $C$ is a direct sum of countably many copies of $\mathbb{Z}$, we may assume that $C \subseteq D$ where $D$ is a direct sum of countably many copies of $\mathbb{Q}$. Thus $D$ is a divisible closure of $C$.

Let us say that a finite set $X \subseteq D$ is *good* if $(X) \cap C \subseteq K$, where $(X)$ is the subgroup of $D$ generated by $X$. We claim that the set of all (codes for) good finite subsets of $D$ exists. To see this, let $X = \{b_i\colon i < k\}$ and let $m_i$ be the least $m \geq 1$ such that $mb_i \in C$. For $X$ to be good it is necessary that $m_i b_i \in K$ and in this case $\sum n_i b_i \in K$ if and only if $\sum r_i b_i \in K$, where $r_i$ is the residue of $n_i$ modulo $m_i$. Thus to determine whether $X$ is good we need only examine finitely many elements of $(X)$, namely the elements $\sum r_i b_i$ where $0 \leq r_i < m_i$, $i < k$. Our claim follows by $\Delta^0_1$ comprehension.

Let $\langle d_i\colon i \in \mathbb{N}\rangle$ be a one-to-one enumeration of the elements of $D$. Define $f\colon \mathbb{N} \to \{0,1\}$ by primitive recursion putting $f(j) = 1$ if and only if $\{d_i\colon i < j \wedge f(i) = 1\} \cup \{d_j\}$ is good, $f(j) = 0$ otherwise. Let $L$ be the set of all $d_i \in D$ such that $f(i) = 1$. Thus $L$ is a subgroup of $D$ and $L \cap C = K$. Putting $B = D/L$ we see that $B$ is divisible and there is a canonical monomorphism of $A = C/K$ into $B$. Also, by the construction of $L$, for any $b \in D \setminus L$ there exists $n \in \mathbb{N}$ such that $nb + d \in C \setminus K$ for some $d \in L$. Hence $B = D/L$ is a divisible closure of $A$. This completes the proof of theorem III.6.4. □

Before discussing uniqueness of divisible closure, let us mention one more concept. A countable Abelian group $D$ is said to be *injective* if, for any homomorphism $h\colon A \to D$ and monomorphism $f\colon A \to B$, where $A$ and $B$ are countable Abelian groups, there exists a homomorphism $h'\colon B \to D$ such that $h'(f(a)) = h(a)$ for all $a \in A$. In $\mathsf{RCA}_0$ we can easily prove that injectivity of $D$ implies divisibility of $D$. (Consider homomorphisms from $\mathbb{Z}$ into $D$ and their extensions to $\mathbb{Q}$.) The proof that divisibility implies injectivity requires $\mathsf{ACA}_0$, as we shall now show.

Theorem III.6.5 (uniqueness of divisible closure). *The following statements are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *Every countable divisible Abelian group is injective.*
3. *The divisible closure of a countable Abelian group is unique.*

PROOF. We begin by proving that 1 implies 2. Reasoning in $\mathsf{ACA}_0$, let $D$ be a countable divisible Abelian group and let $h: A \to D$ be given where A is a subgroup of a countable Abelian group $B$. For any $b \in B$ let $(b)$ be the subgroup of $B$ generated by $b$. Let $\langle b_n : n \in \mathbb{N}\rangle$ be an enumeration of the elements of $B$ and for each $n$ let $A_n$ be the subgroup of $B$ generated by $A \cup \{b_0, \ldots, b_{n-1}\}$. We extend $h$ to $B$ by stages. Assume that we have already extended $h$ to $A_n$. If $(b_n) \cap A_n = (0)$ define $h(b_n) = 0$. If $(b_n) \cap A_n \neq (0)$ let $k_n$ be the least $k \geq 1$ such that $kb_n \in A_n$. Select $d \in D$ such that $k_n d = h(k_n b_n)$ and define $h(b_n) = d$. This gives a homomorphism of $A_{n+1}$ into $D$ since each element of $A_{n+1}$ can be written uniquely in the form $a + jb_n$, $a \in A_n$, $0 \leq j < k_n$. Finally we extend $h$ to all of $B$. Thus $D$ is injective. This proves the implication from 1 to 2.

Next we prove that 2 implies 3. Reasoning in $\mathsf{RCA}_0$, assume 2 and let $h_i: A \to D_i$, $i = 1, 2$, be divisible closures of a countable Abelian group $A$. By injectivity of $D_2$ let $h: D_1 \to D_2$ be such that $h(h_1(a)) = h_2(a)$ for all $a \in A$. Given $d_1 \in D_1$, $d_1 \neq 0$, let $a \in A$ be such that $a \neq 0$ and $h_1(a) = nd_1$ for some $n \in \mathbb{N}$. Then $nh(d_1) = h(nd_1) = h(h_1(a)) = h_2(a) \neq 0$ so $h(d_1) \neq 0$. Thus $h: D_1 \to D_2$ is a monomorphism. By injectivity of $D_1$ let $g: D_2 \to D_1$ be such that $g(h(d)) = d$ for all $d \in D_1$. Clearly $g: D_2 \to D_1$ is an epimorphism. Given $d_2 \in D_2$, $d_2 \neq 0$, let $a \in A$ be such that $a \neq 0$ and $h_2(a) = nd_2$ for some $n \in \mathbb{N}$. Then $ng(d_2) = g(nd_2) = g(h_2(a)) = g(h(h_1(a))) = h_1(a) \neq 0$ so $g(d_2) \neq 0$. Thus $g: D_2 \to D_1$ is a monomorphism and therefore an isomorphism of $D_2$ onto $D_1$. Moreover $g(h_2(a)) = g(h(h_1(a))) = h_1(a)$ for all $a \in A$. Thus the two divisible closures $h_i: A \to D_i$, $i = 1, 2$, are isomorphic over $A$. This proves the implication from 2 to 3.

It remains to prove that 3 implies 1. We reason in $\mathsf{RCA}_0$. Assume 3. Instead of proving $\mathsf{ACA}_0$ directly we shall prove the equivalent statement III.1.3.3. Let $f: \mathbb{N} \to \mathbb{N}$ be a given one-to-one function. Let $\langle p_k : k \in \mathbb{N}\rangle$ be the enumeration of the rational primes in increasing order, i.e., $p_0 = 2$, $p_1 = 3$, $p_2 = 5$, .... Let $A$ be the countable Abelian group given by generators $x$, $y_{ij}$, $z_{ij}$, $i \in \mathbb{N}$, $j \in \mathbb{N}$, and relations $x = y_{i0} = z_{i0}$, $y_{ij} = p_{f(i)} y_{i,j+1}$, $z_{ij} = p_{f(i)} z_{i,j+1}$. The elements of $A$ may be described as finite formal sums

$$kx + \sum m_{ij} y_{ij} + \sum n_{ij} z_{ij} \tag{6}$$

where $k \in \mathbb{Z}$, $0 \leq m_{ij} < p_{f(i)}$, $0 \leq n_{ij} < p_{f(i)}$, $j \geq 1$. Let $D_0$ be the subgroup of $A$ generated by the elements $d_{ij} = y_{ij} - z_{ij}$. $D_0$ exists by $\Delta^0_1$ comprehension since (6) belongs to $D_0$ if and only if $kx + \sum (m_{ij} + n_{ij}) y_{ij} = 0$. Note also that $A = A_1 \oplus D_0 = A_2 \oplus D_0$ where $A_1$ and $A_2$ are the subgroups of $A$ generated by the elements $y_{ij}$ and $z_{ij}$ respectively.

We claim that $D_0$ is divisible. To see this, let $p$ be a prime. If $p = p_{f(i)}$ then $d_{ij} = p d_{i,j+1}$. If $p \neq p_{f(i)}$ let $m, n \in \mathbb{Z}$ be such that $mp + n p^j_{f(i)} = 1$.

Then $d_{ij} = (mp + np^j_{f(i)})d_{ij} = mpd_{ij}$. So $d_{ij}$ is divisible by $p$ for all primes $p$. By an easy application of $\Sigma^0_1$ induction it follows that $D_0$ is divisible.

Put $D = \mathbb{Q} \oplus D_0$ and define monomorphisms $h_1, h_2 \colon A \to D$ by $h_1(y_{ij}) = h_2(z_{ij}) = (p^{-j}_{f(i)}, 0)$, $h_1(z_{ij}) = h_2(y_{ij}) = (p^{-j}_{f(i)}, d_{ij})$. By the previous claim, $h_i \colon A \to D$, $i = 1, 2$ are divisible closures of $A$. By 3 let $h \colon D \to D$ be an automorphism of $D$ such that $h(h_1(a)) = h_2(a)$ for all $a \in A$. By $\Delta^0_1$ comprehension let $X$ be the set of all $k$ such that $h((p_k^{-1}, 0)) \neq (p_k^{-1}, 0)$. We claim that $\forall k\,(k \in X \leftrightarrow \exists i\,(f(i) = k))$. If $k = f(i)$ then we have $h((p_k^{-1}, 0)) = h(h_1(y_{i1})) = h_2(y_{i1}) = (p_k^{-1}, d_{i1}) \neq (p_k^{-1}, 0)$ so $k \in X$. If $k \neq f(i)$ for all $i$, then we have $p_k h((p_k^{-1}, 0)) = h((1, 0)) = h(h_1(y_{i0})) = h_2(y_{i0}) = (1, 0)$ so $h((p_k^{-1}, 0)) = (p_k^{-1}, 0)$ since $D_0$ has no $p_k$-torsion. Thus $k \notin X$ in this case. Our claim is proved. By lemma III.1.3 this gives $\mathsf{ACA}_0$. The proof of the theorem is complete. □

Remark III.6.6 (strong divisible closure). Let $A$ be a countable Abelian group. A *strong divisible closure* of $A$ is a divisible closure $h \colon A \to D$ such that $h$ is an isomorphism of $A$ onto a subgroup of $D$. Solomon [251, theorem 6.21] has shown that $\mathsf{ACA}_0$ is equivalent over $\mathsf{RCA}_0$ to the statement that every countable Abelian group has a strong divisible closure.

**Notes for §III.6.** The main results of this section are from Friedman/Simpson/Smith [78]. For general information on Abelian groups, see Fuchs [83] or Kaplansky [136].

## III.7. König's Lemma and Ramsey's Theorem

In this section we consider two basic results of infinitary combinatorics, König's lemma and Ramsey's theorem. We show that these results are provable in $\mathsf{ACA}_0$. We also obtain reversals by showing that each of the two results is equivalent to $\mathsf{ACA}_0$ over $\mathsf{RCA}_0$.

We first discuss König's lemma. It is important to distinguish between König's lemma and what we shall later call weak König's lemma. *König's lemma* says that every infinite, finitely branching tree has a path. *Weak König's lemma* makes this assertion only for trees of sequences of 0's and 1's. Weak König's lemma is very important and will be discussed throughly in the next chapter. The discussion here in chapter III refers only to the full König's lemma.

Definition III.7.1 (König's lemma). The following definitions are made in $\mathsf{RCA}_0$. A *tree* is a set $T \subseteq \mathbb{N}^{<\mathbb{N}}$ which is closed under initial segment, i.e., $\forall\sigma\,\forall\tau\,((\sigma \in \mathbb{N}^{<\mathbb{N}} \wedge \sigma \subseteq \tau \wedge \tau \in T) \to \sigma \in T)$. We say that $T$ is *finitely branching* if each element of $T$ has only finitely many

immediate successors, i.e., $\forall\sigma\,(\sigma \in T \to \exists n\,\forall m\,(\sigma^\frown\langle m\rangle \in T \to m < n))$. A *path* through $T$ is a function $g\colon \mathbb{N} \to \mathbb{N}$ such that $g[n] \in T$ for all $n \in \mathbb{N}$. Here we are using the initial sequence notation

$$g[n] = \langle g(0), g(1), \ldots, g(n-1)\rangle.$$

*König's lemma* is the assertion that every infinite, finitely branching tree $T$ has at least one path.

THEOREM III.7.2. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *König's lemma*.
3. *König's lemma restricted to trees* $T \subseteq \mathbb{N}^{<\mathbb{N}}$ *such that* $\forall\sigma\,(\sigma \in T \to \sigma$ *has only at most two immediate successors in* $T)$.

PROOF. We first prove König's lemma from $\mathsf{ACA}_0$. Let $T \subseteq \mathbb{N}^{<\mathbb{N}}$ be an infinite, finitely branching tree. By arithmetical comprehension let $T^*$ be the set of all $\tau \in T$ such that there exist infinitely many $\sigma \in T$ such that $\sigma \supseteq \tau$. Since $T$ is infinite, the empty sequence $\langle\rangle$ belongs to $T^*$. Since $T$ is finitely branching, each $\tau \in T^*$ has at least one immediate successor $\tau^\frown\langle n\rangle \in T^*$. Thus we may use primitive recursion to define a path $g$ by $g(k) =$ least $n$ such that $g[k]^\frown\langle n\rangle \in T^*$. Thus $g[k]$ is an initial sequence of $g$ of length $k$. This proves that 1 implies 2.

The implication from 2 to 3 is trivial, so it remains to prove that 3 implies 1. We reason in $\mathsf{RCA}_0$. Assume 3 and let $f\colon \mathbb{N} \to \mathbb{N}$ be one-to-one. By lemma III.1.3 it suffices to prove that the range of $f$ exists, i.e., $\exists X\,\forall n\,(n \in X \leftrightarrow \exists m\,(f(m) = n))$. Define a tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ by putting $\tau \in T$ if and only if

$$(\forall m < \mathrm{lh}(\tau))\,(\forall n < \mathrm{lh}(\tau))\,(f(m) = n \leftrightarrow \tau(n) = m + 1) \tag{7}$$

and

$$(\forall n < \mathrm{lh}(\tau))\,(\tau(n) > 0 \to f(\tau(n) - 1) = n). \tag{8}$$

Clearly $T$ exists by $\Sigma^0_0$ comprehension. If $\sigma \in T$ then $\sigma$ has at most two immediate successors in $T$, since by (8) the only possiblities are $\sigma^\frown\langle 0\rangle$ and $\sigma^\frown\langle m+1\rangle$ where $f(m) = \mathrm{lh}(\sigma)$. To see that $T$ is infinite, let $k \in \mathbb{N}$ be given. By bounded $\Sigma^0_1$ comprehension (theorem II.3.9), let $Y$ be the set of all $n < k$ such that $\exists m\, f(m) = n$. Define $\sigma \in \mathbb{N}^{<\mathbb{N}}$, $\mathrm{lh}(\sigma) = k$ by putting

$$\sigma(n) = \begin{cases} 0 & \text{if } n \notin Y \\ m+1 & \text{if } n \in Y \wedge f(m) = n \end{cases}$$

for all $n < k$. It is easy to check that $\sigma \in T$. This shows that $T$ is infinite. Hence by 3 there exists a path $g$ though $T$. From (7) it is clear that $\forall m\,\forall n\,(f(m) = n \leftrightarrow g(n) = m + 1)$. By $\Delta^0_1$ comprehension let $X$ be

the set of all $n$ such that $g(n) > 0$. Then $\forall n\,(\exists m\,(f(m) = n) \leftrightarrow n \in X)$. This completes the proof of theorem III.7.2. □

We now turn to Ramsey's theorem.

Definition III.7.3 (Ramsey's theorem). The following definitions are made in $\mathsf{RCA}_0$. For any $X \subseteq \mathbb{N}$ and $k \in \mathbb{N}$, let $[X]^k$ be the set of all increasing sequences of length $k$ of elements of $X$. In symbols, $s \in [X]^k$ if and only if $s \in \mathbb{N}^k$ and $(\forall j < k)\,(s(j) \in X \wedge (\forall i < j)\,(s(i) < s(j)))$. By $\mathrm{RT}(k)$, i.e., *Ramsey's theorem for exponent* $k$, we mean the assertion that for all $l \in \mathbb{N}$ and all $f : [\mathbb{N}]^k \to \{0, 1, \ldots, l-1\}$, there exist $i < l$ and an infinite set $X \subseteq \mathbb{N}$ such that $f(m_1, \ldots, m_k) = i$ for all $\langle m_1, \ldots, m_k\rangle \in [X]^k$.

The following lemma implies that for each $k \in \omega$, $\mathrm{RT}(k)$ is provable in $\mathsf{ACA}_0$.

Lemma III.7.4. $\mathsf{ACA}_0$ *proves* $\mathrm{RT}(0)$ *and*

$$\forall k\,(\mathrm{RT}(k) \to \mathrm{RT}(k+1)).$$

Proof. We reason in $\mathsf{ACA}_0$ and imitate a popular proof of Ramsey's theorem based on König's lemma. (Ramsey's original proof is simpler but apparently cannot be carried out in $\mathsf{ACA}_0$.)

$\mathrm{RT}(0)$ is trivial. Assume $\mathrm{RT}(k)$ and let

$$f : [\mathbb{N}]^{k+1} \to \{0, 1, \ldots, l-1\}$$

be given. Define a tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ by putting $t \in T$ if and only if, for all $n < \mathrm{lh}(t)$, $t(n)$ is the least $j$ such that

(i) $t(m) < j$ for all $m < n$,

and

(ii) $f(t(m_1), \ldots, t(m_k), j) = f(t(m_1), \ldots, t(m_k), t(m))$ for all $m_1 < \cdots < m_k < m \leq n$.

Clearly $T$ is a tree and $T$ exists by $\Sigma^0_0$ comprehension. Also $T$ is finitely branching since, given $t \in T$ of length $n$, there are $\leq l^{n^k}$ distinct $j$ such that $t^\frown\langle j\rangle \in T$. Among combinatorists $T$ is known as the *Erdős/Radó tree*.

We claim that for each $j$ there exists $s \in T$ such that $s(n) = j$ for some $n < \mathrm{lh}(s)$. To see this, fix $j$ and let $t \in T$ be maximal such that $t(m) < j$ for all $m < \mathrm{lh}(t)$, and $f(t(m_1), \ldots, t(m_k), t(m)) = f(t(m_1), \ldots, t(m_k), j)$ for all $m_1 < \cdots < m_k < m < \mathrm{lh}(t)$. (There is at least one such $t$, namely $t = \langle\rangle$, the empty sequence.) Then clearly $t^\frown\langle j\rangle \in T$. This proves the claim.

The previous claim implies that $T$ is infinite. Hence, by König's lemma in $\mathsf{ACA}_0$ (theorem III.7.1), $T$ has a path, call it $g$. From (i) we have that $m < n$ implies $g(m) < g(n)$. Define $f' : [\mathbb{N}]^k \to \{0, 1, \ldots, l-1\}$ by $f'(m_1, \ldots, m_k) = f(g(m_1), \ldots, g(m_k), g(m))$ where $m_1 < \cdots < m_k < m$; by (ii) this does not depend on the choice of $m$. Using $\mathrm{RT}(k)$ let

$i < l$ and $X' \subseteq \mathbb{N}$ be such that $X'$ is infinite and $f'(m_1, \ldots, m_k) = i$ for all $\langle m_1, \ldots, m_k \rangle \in [X']^k$. Then clearly $f(m_1, \ldots, m_k, m) = i$ for all $\langle m_1, \ldots, m_k, m \rangle \in [X]^{k+1}$, where $X$ is the set of all $g(m)$, $m \in X'$. This proves $\mathrm{RT}(k+1)$. The proof of the lemma is complete. □

LEMMA III.7.5. *It is provable in* $\mathsf{RCA}_0$ *that* $\mathrm{RT}(3)$ *implies* $\mathsf{ACA}_0$.

PROOF. Assume $\mathrm{RT}(3)$. By theorem III.1.3 it suffices to prove $\Sigma^0_1$ comprehension. Given a $\Sigma^0_1$ formula $\varphi(m)$ we want to prove $\exists Z \, \forall m \, (m \in Z \leftrightarrow \varphi(m))$. Let $\varphi(m) \equiv \exists n \, \theta(m, n)$ where $\theta(m, n)$ is $\Sigma^0_0$. Define $f : [\mathbb{N}]^3 \to \{0, 1\}$ by putting $f(a, b, c) = 1$ if

$$(\forall m < a) \, ((\exists n < b) \, \theta(m, n) \leftrightarrow (\exists n < c) \, \theta(m, n)), \tag{9}$$

$f(a, b, c) = 0$ otherwise. By $\mathrm{RT}(3)$ let $i < 2$ and $X \subseteq \mathbb{N}$ be such that $X$ is infinite and $f(a, b, c) = i$ for all $\langle a, b, c \rangle \in [X]^3$.

We claim that $i = 1$. It suffices to show that $f(a, b, c) = 1$ for at least one 3-tuple $\langle a, b, c \rangle \in [X]^3$. Let $a$ be any element of $X$. By bounded $\Sigma^0_1$ comprehension (theorem II.3.9), let $Y$ be the set of all $m < a$ such that $\exists n \, \theta(m, n)$. By $\Sigma^0_1$ induction we can prove that $\forall j \, \exists k \, (\forall m < j) \, (m \in Y \to (\exists n < k) \theta(m, n))$. In particular, taking $j = a$, we find that there exists $k$ such that $\forall m \, (m \in Y \to (\exists n < k) \, \theta(m, n))$. Since $X$ is infinite there exist $b \in X$, $c \in X$ such that $a < b < c$ and $k \leq b$. Thus $\langle a, b, c \rangle \in [X]^3$ and (9) holds. Hence $f(a, b, c) = 1$. This proves the claim.

Since $i = 1$ and $X$ is infinite, we have $\exists n \, \theta(m, n)$ if and only if $\forall a \, \forall b \, ((a \in X \wedge b \in X \wedge m < a < b) \to (\exists n < b) \, \theta(m, n))$. Hence by $\Delta^0_1$ comprehension there exist $Z$ such that $\forall m \, (m \in Z \leftrightarrow \exists n \, \theta(m, n))$. This completes the proof. □

THEOREM III.7.6. *Over* $\mathsf{RCA}_0$, $\mathsf{ACA}_0$ *is equivalent to* $\mathrm{RT}(3)$. (*Here we could replace* $\mathrm{RT}(3)$ *by any* $\mathrm{RT}(k)$, $k \geq 3$, $k \in \omega$.)

PROOF. Immediate from lemmas III.7.4 and III.7.5. □

REMARKS III.7.7. (1) The case $k = 2$ is anomalous. On the one hand, it is known that $\mathsf{WKL}_0$ does not prove $\mathrm{RT}(2)$. In fact, there exists an $\omega$-model of $\mathsf{WKL}_0$ in which $\mathrm{RT}(2)$ fails. On the other hand, there exists an $\omega$-model $M$ of $\mathsf{WKL}_0 + \mathrm{RT}(2)$ which does not contain $\emptyset^{(1)}$, hence $\mathsf{ACA}_0$ fails in $M$. For bibliographical references, see the notes at the end of this section. (2) It is known that $\forall k \, \mathrm{RT}(k)$ is not provable in $\mathsf{ACA}_0$. However, by lemma III.7.4, $\forall k \, \mathrm{RT}(k)$ is provable from $\mathsf{ACA}_0$ plus $\Pi^1_2$ induction.

We have now completed our discussion of König's lemma and Ramsey's theorem. We end this section with a brief discussion of the Radó selection lemma.

The *Radó selection lemma* is a well known combinatorial principle which plays an important role in transversal theory. Its general statement is as follows. Let $X$ be an arbitrary set and let $\mathcal{F}$ be a family of functions such

that $(\forall f \in \mathcal{F})(\mathrm{dom}(f) \subseteq X)$ and $(\forall \text{ finite } X_0 \subseteq X)(\exists f \in \mathcal{F})(X_0 \subseteq \mathrm{dom}(f))$. Assume that $\forall x \in X(\{f(x): f \in \mathcal{F} \wedge x \in \mathrm{dom}(f)\} \text{ is finite})$. Then there exists a function $F$ such that $\mathrm{dom}(F) = X$ and $(\forall \text{ finite } X_0 \subseteq X)(\exists f \in \mathcal{F})(X_0 \subseteq \mathrm{dom}(f) \wedge f \restriction X_0 = F \restriction X_0)$.

We consider two versions of the special case of the Radó selection lemma in which the underlying set $X$ is countable. For convenience we take $X = \mathbb{N}$.

Theorem III.7.8 (Radó selection lemma). *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. (countable Radó lemma, strong version) *Let* $\langle f_i : i \in \mathbb{N} \rangle$ *be a sequence of partially defined functions from* $\mathbb{N}$ *into* $\mathbb{N}$. *Assume that* $(\forall \text{finite } X \subseteq \mathbb{N})\exists i\,(X \subseteq \mathrm{dom}(f_i))$ *and that* $\forall m \exists n \forall i\,(m \in \mathrm{dom}(f_i) \to f_i(m) < n)$. *Then there exists* $f : \mathbb{N} \to \mathbb{N}$ *such that* $(\forall \text{finite } X \subseteq \mathbb{N})\exists i\,(X \subseteq \mathrm{dom}(f_i) \wedge f \restriction X = f_i \restriction X)$.
3. (countable Radó lemma, weak version) *Given a sequence of finite functions* $\langle f_n : n \in \mathbb{N} \rangle$, $f_n : \{0, 1, \ldots, n\} \to \{0, 1\}$, *there exists* $f : \mathbb{N} \to \{0, 1\}$ *such that* $\forall m \exists n\,(m \leq n \wedge f \restriction \{0, 1, \ldots, m\} = f_n \restriction \{0, 1, \ldots, m\})$.

Proof. The proof is left as an exercise for the reader. □

**Notes for §III.7.** The original source for König's lemma is König [147]. Theorem III.7.2 has been stated without proof by Friedman [68, 69]. For a thorough discussion of Ramsey's theorem, including a facsimile of Ramsey's original proof, see Graham/Rothschild/Spencer [98]. Theorem III.7.6 is due to Simpson (unpublished) and is closely related to earlier results of Jockusch [133] and Paris [200]. The existence of an $\omega$-model of $\mathsf{WKL}_0$ in which $\mathrm{RT}(2)$ fails is due to Hirst [117, theorem 6.10] using a result of Jockusch [133, theorem 3.1]. The existence of an $\omega$-model of $\mathsf{WKL}_0 + \mathrm{RT}(2)$ in which $\mathsf{ACA}_0$ fails is due to Seetapun; see Hummel [125]. Optimal results on the strength of $\mathsf{RCA}_0 + \mathrm{RT}(2)$ are in Cholak/Jockusch/Slaman [36]. For more information on the Radó selection lemma and its role in transversal theory, see Mirsky [190]. Theorem III.7.8 is due jointly to Feng and Simpson; see Hirst [117, theorem 3.30].

## III.8. Conclusions

We began this chapter by defining $\mathsf{ACA}_0$ to consist of $\mathsf{RCA}_0$ plus arithmetical comprehension. We then demonstrated that $\mathsf{ACA}_0$ is considerably stronger than $\mathsf{RCA}_0$ from the viewpoint of mathematical practice. Indeed, several mathematical theorems are equivalent over $\mathsf{RCA}_0$ to $\mathsf{ACA}_0$. Among these are: the least upper bound principle for sequences of real numbers (§III.2); sequential compactness of the closed unit interval $[0, 1]$

and of compact metric spaces (§III.2); existence of the strong algebraic closure of an arbitrary countable field (§III.3); the fact that every countable vector space over $\mathbb{Q}$ has a basis (§III.4); the fact that every countable commutative ring has a maximal ideal (§III.5); uniqueness of the divisible closure of an arbitrary countable Abelian group (§III.6); König's lemma for subtrees of $\mathbb{N}^{<\mathbb{N}}$, and Ramsey's theorem for colorings of $[\mathbb{N}]^3$ (§III.7). These equivalences provide our first illustrations of the theme of Reverse Mathematics.

Chapter IV

# WEAK KÖNIG'S LEMMA

## IV.1. The Heine/Borel Covering Lemma

The purpose of this chapter is to study a certain subsystem of second order arithmetic known as $\mathsf{WKL}_0$. In order to define $\mathsf{WKL}_0$, let $2^{<\mathbb{N}}$ (also denoted $\{0,1\}^{<\mathbb{N}}$) be the set of all (codes for) finite sequences of 0's and 1's, i.e., the set of all $s \in \mathbb{N}^{<\mathbb{N}}$ such that $\forall i\,(i < \mathrm{lh}(s) \rightarrow s(i) < 2)$. *Weak König's lemma* is the statement that every infinite tree $T \subseteq 2^{<\mathbb{N}}$ has a path. The axioms of $\mathsf{WKL}_0$ are those of $\mathsf{RCA}_0$ plus weak König's lemma.

By theorem III.7.2, the theorems of $\mathsf{WKL}_0$ are included in those of $\mathsf{ACA}_0$. It will become clear in §VIII.2 that this inclusion is strict. Hence by theorem III.2.2 it follows that $\mathsf{WKL}_0$ is not strong enough to prove the Bolzano/Weierstraß theorem, i.e., sequential compactness of the closed unit interval $0 \leq x \leq 1$. However, we shall show in this section that $\mathsf{WKL}_0$ is strong enough to prove the *Heine/Borel theorem*: Every covering of the closed unit interval $0 \leq x \leq 1$ by a sequence of open intervals has a finite subcovering. We shall then generalize this to compact metric spaces.

Also in this section we shall obtain a reversal showing that the Heine/Borel theorem is in fact equivalent to $\mathsf{WKL}_0$ over $\mathsf{RCA}_0$. In subsequent sections of this chapter, we shall show that $\mathsf{WKL}_0$ is equivalent over $\mathsf{RCA}_0$ to several other ordinary mathematical theorems. Among those theorems are: the Gödel completeness theorem (§IV.3); the theorem that every continuous function on the closed unit interval $0 \leq x \leq 1$ attains a maximum value (§IV.2); the uniqueness theorem for countable algebraic closures (§IV.5); a theorem of Artin and Schreier concerning orderability of (countable) fields (§IV.4); the theorem that every countable commutative ring has a prime ideal (§IV.6); Brouwer's fixed point theorem (§IV.7); Peano's existence theorem for solutions of ordinary differential equations (§IV.8); and the Hahn/Banach theorem for separable Banach spaces (§IV.9). These results provide further illustrations of the theme of Reverse Mathematics.

LEMMA IV.1.1 (Heine/Borel theorem for $[0,1]$). *The following is provable in* $\mathsf{WKL}_0$. *Given sequences of real numbers* $c_i, d_i$, $i \in \mathbb{N}$, *if*

$$\forall x\,(0 \le x \le 1 \to \exists i\,(c_i < x < d_i)),$$

*then*

$$\exists n\,\forall x\,(0 \le x \le 1 \to \exists i \le n\,(c_i < x < d_i)).$$

PROOF. Reasoning in $\mathsf{WKL}_0$, we shall first prove the theorem under the assumption that $\langle c_i : i \in \mathbb{N}\rangle$ and $\langle d_i : i \in \mathbb{N}\rangle$ are sequences of rational numbers.

For each $s \in 2^{<\mathbb{N}}$ put

$$a_s = \sum_{i<\mathrm{lh}(s)} \frac{s(i)}{2^{i+1}}$$

and

$$b_s = a_s + \frac{1}{2^{\mathrm{lh}(s)}}.$$

Thus for each $n \in \mathbb{N}$ we have partitioned the unit interval $0 \le x \le 1$ into $2^n$ subintervals of length $2^{-n}$, namely $a_s \le x \le b_s$, $s \in 2^{<\mathbb{N}}$, $\mathrm{lh}(s) = n$. Form a tree $T \subseteq 2^{<\mathbb{N}}$ by putting $s \in T$ if and only if $\neg\exists i \le \mathrm{lh}(s)\,(c_i < a_s < b_s < d_i)$. $T$ exists by $\Sigma^0_0$ comprehension since $c_i, d_i, a_s, b_s \in \mathbb{Q}$.

Assuming that $\forall x\,(0 \le x \le 1 \to \exists i\,(c_i < x < d_i))$, we claim that $T$ has no path. To see this let $f : \mathbb{N} \to \{0,1\}$ be given and put

$$x = \sum_{j=0}^{\infty} \frac{f(j)}{2^{j+1}},$$

i.e., the unique $x$ such that $a_{f[n]} \le x \le b_{f[n]}$ for all $n \in \mathbb{N}$. Let $i$ be such that $c_i < x < d_i$ and let $n$ be so large that $n \ge i$ and $c_i < a_{f[n]} < b_{f[n]} < d_i$. Then $f[n] \notin T$ which proves the claim.

By weak König's lemma it follows that $T$ is finite. Let $n$ be such that $\forall s\,(s \in T \to \mathrm{lh}(s) < n)$. Then $\forall s\,(\mathrm{lh}(s) = n \to \exists i \le n\,(c_i < a_s < b_s < d_i))$. Hence $\forall x\,(0 \le x \le 1 \to \exists i \le n\,(c_i < x < d_i))$.

This proves the theorem under the assumption that $c_i, d_i \in \mathbb{Q}$. In general, consider the $\Sigma^0_1$ formula $\varphi(q,r)$ which says that $q \in \mathbb{Q} \wedge r \in \mathbb{Q} \wedge \exists i\,(c_i < q < r < d_i)$. By lemma II.3.7 there exists a function $f : \mathbb{N} \to \mathbb{Q} \times \mathbb{Q}$ such that $\forall q\,\forall r\,(\varphi(q,r) \leftrightarrow \exists j\,(f(j) = (q,r)))$. Thus we may replace the sequence $\langle (c_i, d_i) : i \in \mathbb{N}\rangle$ by the sequence $\langle (q_j, r_j) : j \in \mathbb{N}\rangle$ where $(q_j, r_j) = f(j)$. This reduces the theorem to the special case which has already been proved. □

THEOREM IV.1.2. $\mathsf{WKL}_0$ *is equivalent over* $\mathsf{RCA}_0$ *to the Heine/Borel theorem for* $[0,1]$.

PROOF. The previous lemma shows that $\mathsf{WKL}_0$ proves Heine/Borel for $[0,1]$. Reasoning in $\mathsf{RCA}_0$, assume Heine/Borel for $[0,1]$. We shall make use of the Cantor middle-third set $C \subseteq [0,1]$ consisting of all real numbers of the form

$$\sum_{i=0}^{\infty} \frac{2f(i)}{3^{i+1}}, \qquad f \in 2^{\mathbb{N}}.$$

The idea of the proof will be that paths through $2^{<\mathbb{N}}$ can be identified with elements of $C$, so Heine/Borel compactness of $2^{\mathbb{N}}$ follows from Heine/Borel compactness of the closed unit interval $0 \leq x \leq 1$.

For each $s \in 2^{<\mathbb{N}}$ put

$$a_s = \sum_{i<\mathrm{lh}(s)} \frac{2s(i)}{3^{i+1}}$$

and

$$b_s = a_s + \frac{1}{3^{\mathrm{lh}(s)}}.$$

Thus $a_{\langle\rangle} = 0$, $b_{\langle\rangle} = 1$, and the closed interval $a_{s^\frown\langle 0\rangle} \leq x \leq b_{s^\frown\langle 0\rangle}$ (respectively $a_{s^\frown\langle 1\rangle} \leq x \leq b_{s^\frown\langle 1\rangle}$) is the left third (respectively the right third) of the closed interval $a_s \leq x \leq b_s$. Thus for each $x \in C$ there is a unique $f : \mathbb{N} \to \{0,1\}$ such that $a_{f[n]} \leq x \leq b_{f[n]}$ for all $n \in \mathbb{N}$. Also, if $0 \leq x \leq 1$ and $x \notin C$, then $b_{s^\frown\langle 0\rangle} < x < a_{s^\frown\langle 1\rangle}$ for a unique $s \in 2^{<\mathbb{N}}$.

We also put

$$a'_s = a_s - \frac{1}{3^{\mathrm{lh}(s)+1}}$$

and

$$b'_s = b_s + \frac{1}{3^{\mathrm{lh}(s)+1}}$$

Note that the open intervals $a'_s < x < b'_s$ and $a'_t < x < b'_t$ are disjoint unless $s \subseteq t$ or $t \subseteq s$.

Let $T \subseteq 2^{<\mathbb{N}}$ be a tree with no path. We shall use the Heine/Borel theorem to show that $T$ is finite. Let $\widetilde{T}$ be the set of $u \in 2^{<\mathbb{N}}$ such that $u \notin T \wedge \forall t\,(t \subsetneqq u \to t \in T)$. Then the open intervals $a'_u < x < b'_u$, $u \in \widetilde{T}$, are pairwise disjoint and cover $C$. Hence the closed unit interval $0 \leq x \leq 1$ is covered by the open intervals

$$a'_u < x < b'_u, \qquad u \in \widetilde{T}$$

and

$$b_{s^\frown\langle 0\rangle} < x < a_{s^\frown\langle 1\rangle}, \qquad s \in 2^{<\mathbb{N}}.$$

By the Heine/Borel theorem, this covering has a finite subcovering. But the intervals $b_{s^\frown\langle 0\rangle} < x < a_{s^\frown\langle 1\rangle}$ are disjoint from $C$ and clearly $C$ is not

covered by any proper subset of the intervals $a'_u < x < b'_u$, $u \in \widetilde{T}$. Hence $\widetilde{T}$ is finite. This completes the proof. □

In the remainder of this section, we generalize lemma IV.1.1 to the case of compact metric spaces (as defined in §III.2). For this we need the following generalization of weak König's lemma.

DEFINITION IV.1.3 (bounded König's lemma). Within $\mathsf{RCA}_0$, a tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ is said to be *bounded* if there exists a function $g : \mathbb{N} \to \mathbb{N}$ such that for all $\tau \in T$ and $m < \mathrm{lh}(\tau)$, $\tau(m) < g(m)$. *Bounded König's lemma* is the assertion that every bounded infinite tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ has a path.

LEMMA IV.1.4. *Weak König's lemma is equivalent over* $\mathsf{RCA}_0$ *to bounded König's lemma.*

PROOF. Any subtree of $2^{<\mathbb{N}}$ is bounded by the constant function 2. Therefore bounded König's lemma trivially implies weak König's lemma. For the converse, let an infinite bounded tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ be given. Let $g : \mathbb{N} \to \mathbb{N}$ be a bounding function, i.e., $\tau(j) < g(j)$ for all $\tau \in T$, $j < \mathrm{lh}(\tau)$. Given $\tau \in T$, define $\tau^* \in 2^{<\mathbb{N}}$ by putting

$$\tau^*\left(\sum_{i=0}^{j-1} g(i) + k\right) = \begin{cases} 0 & \text{if } k < \tau(j), \\ 1 & \text{if } \tau(j) \leq k < g(j), \end{cases}$$

for all $j < \mathrm{lh}(\tau)$. Thus $\mathrm{lh}(\tau^*) = \sum_{i=0}^{m-1} g(i) \geq m$ where $m = \mathrm{lh}(\tau)$. By $\Delta^0_1$ comprehension, let $T^*$ be the set of all $\sigma \in 2^{<\mathbb{N}}$ such that $\sigma \subseteq \tau^*$ for some $\tau \in T$ such that $\tau \leq g[\mathrm{lh}(\sigma)]$. Thus $T^*$ is an infinite subtree of $2^{<\mathbb{N}}$. By weak König's lemma, let $f^* : \mathbb{N} \to \{0, 1\}$ be a path through $T^*$. Define $f : \mathbb{N} \to \mathbb{N}$ by putting $f(j) =$ the least $k$ such that $f^*(\sum_{i=0}^{j-1} g(i)+k) = 1$. Thus $f$ is a path through $T$. This completes the proof. □

THEOREM IV.1.5 (Heine/Borel for compact metric spaces). *The following is provable in* $\mathsf{WKL}_0$. *Let* $\widehat{A}$ *be a compact metric space. If* $\langle U_j : j \in \mathbb{N}\rangle$ *is a covering of* $\widehat{A}$ *by open sets, then there exists a finite subcovering* $\langle U_j : j \leq l\rangle$, $l \in \mathbb{N}$.

PROOF. We reason in $\mathsf{WKL}_0$. Since $\widehat{A}$ is compact, let $\langle\langle x_{ik} : k \leq n_i\rangle : i \in \mathbb{N}\rangle$ be a sequence of finite sequences of points $x_{ik} \in \widehat{A}$ such that for all $y \in \widehat{A}$ and $i \in \mathbb{N}$ there exists $k \leq n_i$ such that $d(x_{ik}, y) < 2^{-i}$. We may safely assume that each $U_j$ is a basic open ball $\mathrm{B}(a_j, r_j)$ where $a_j \in A$, $r_j \in \mathbb{Q}^+$. For any two points $x, y \in \widehat{A}$, we use the notation $d(x, y) = \langle d(x, y)_k : k \in \mathbb{N}\rangle$. Here we are viewing the real number $d(x, y)$ as a sequence of rational numbers (definition II.4.4).

By $\Delta^0_1$ comprehension, form a tree $T$ consisting of all $\tau \in \mathbb{N}^{<\mathbb{N}}$ such that

$$\forall i < \mathrm{lh}(\tau)\,[\tau(i) \leq n_i] \quad \text{and}$$
$$\forall i, j, k < \mathrm{lh}(\tau)\,[d(x_{i,\tau(i)}, x_{j,\tau(j)})_k \leq 2^{-i} + 2^{-j} + 2^{-k}] \quad \text{and}$$
$$\forall i, j, k < \mathrm{lh}(\tau)\,[d(x_{i,\tau(i)}, a_j)_k \geq r_j - 2^{-i} - 2^{-k}].$$

Obviously $T$ is a bounded tree, the bounding function $g$ being given by $g(i) = n_i + 1$. If $f : \mathbb{N} \to \mathbb{N}$ were a path through $T$, there would be a point

$$x = \lim_i x_{i,f(i)} \in \widehat{A}$$

such that $d(x, a_j) \geq r_j$ for all $j \in \mathbb{N}$, i.e., $x$ does not belong to $U_j = \mathrm{B}(a_j, r_j)$ for any $j \in \mathbb{N}$. This shows that $T$ has no path. If follows by bounded König's lemma in $\mathsf{WKL}_0$ (lemma IV.1.4) that $T$ is finite. Let $l$ be the least integer such that $T$ contains no sequence of length $l$. Then clearly $\langle \mathrm{B}(a_j, r_j) : j < l \rangle$ covers $\widehat{A}$. This completes the proof. □

For use in the next section, we mention the following generalization of theorem IV.1.5.

Theorem IV.1.6. *The following is provable in* $\mathsf{WKL}_0$. *Let* $\widehat{A}$ *be a compact metric space. Let* $\langle \langle U_{nj} : j \in \mathbb{N} \rangle : n \in \mathbb{N} \rangle$ *be a sequence of coverings of* $\widehat{A}$ *by open sets. Then there exists a sequence of finite subcoverings* $\langle \langle U_{nj} : j \leq l_n \rangle : n \in \mathbb{N} \rangle$.

Proof. This is a straightforward adaptation of the proof of theorem IV.1.5. We define a sequence of bounded trees $\langle T_n : n \in \mathbb{N} \rangle$ and argue as before that each of the trees in the sequence is finite. □

The following two theorems will be needed in §IV.7.

Theorem IV.1.7. *The following is provable in* $\mathsf{WKL}_0$. *Let* $X$ *be a compact metric space. If* $C$ *denotes a (code for a) closed set in* $X$, *the assertion that* $C \neq \emptyset$ *(i.e.,* $C$ *is nonempty) is expressible by a* $\Pi^0_1$ *formula.*

Proof. We reason in $\mathsf{WKL}_0$. Since $X$ is compact, let $\langle \langle x_{ik} : k \leq n_i \rangle : i \in \mathbb{N} \rangle$ be a sequence of finite sequences of points in $X$ such that for all $y \in X$ and $i \in \mathbb{N}$ there exists $k \leq n_i$ such that $d(x_{ik}, y) < 2^{-i}$. Thus for each $i \in \mathbb{N}$ we have

$$X = \bigcup_{k \leq n_i} \mathrm{B}(x_{ik}, 2^{-i}).$$

Now let $C$ be a closed set in $X$, and let $U$ be a code for the open set $X \setminus C$. Recall from definition II.5.6 that $U$ is actually a subset of $\mathbb{N} \times A \times \mathbb{Q}^+$. A point $x \in X$ belongs to (the open set coded by) $U$ if and only if $d(a, x) < r$ for some $(m, a, r) \in U$. Thus we have

$$X \setminus C = \bigcup_{(m,a,r) \in U} \mathrm{B}(a, r).$$

We claim that $C = \emptyset$ if and only if the following condition $(*)$ holds: there exist $i$ and a finite sequence of triples $(m_k, a_k, r_k) \in U$, $k \leq n_i$, such that $d(x_{ik}, a_k) + 2^{-i} < r_k$ for all $k \leq n_i$. Since this condition is $\Sigma^0_1$, the claim will suffice to prove our theorem.

To prove the claim, assume first that $C = \emptyset$. Then we have

$$X = \bigcup_{(m,a,r)\in U} \bigcup_{0<q<r} \mathrm{B}(a, q)$$

where $q$ ranges over $\mathbb{Q}^+$. Hence by the Heine/Borel property (theorem IV.1.5), there exists a finite sequence of triples $(m_l, a_l, r_l) \in U$, $l \in L$, and $q_l \in \mathbb{Q}^+$, $l \in L$, such that $0 < q_l < r_l$ for all $l \in L$, and

$$X = \bigcup_{l\in L} \mathrm{B}(a_l, q_l).$$

Let $i \in \mathbb{N}$ be such that $2^{-i} < \min_{l\in L}(r_l - q_l)$. Then for each $k \leq n_i$ we have $x_{ik} \in \mathrm{B}(a_{l_k}, q_{l_k})$ for some $l_k \in L$, hence $d(x_{ik}, a_{l_k}) < q_{l_k}$, hence $d(x_{ik}, a_{l_k}) + 2^{-i} < r_{l_k}$. Thus $(*)$ holds. Conversely, if $(*)$ holds, then for all $k \leq n_i$ we have $\mathrm{B}(x_{ik}, 2^{-i}) \subseteq \mathrm{B}(a_k, r_k)$, hence $X = \bigcup_{k\leq n_i} \mathrm{B}(a_k, r_k) \subseteq U$, hence $C = \emptyset$. This completes the proof. □

The following theorem is a kind of choice principle for points in compact sets.

THEOREM IV.1.8. *The following is provable in* $\mathsf{WKL}_0$. *Let $X$ be a compact metric space, and let $C_j$, $j \in \mathbb{N}$, be a sequence of (codes for) nonempty closed sets in $X$. Then there exists a sequence of points $x_j \in C_j$, $j \in \mathbb{N}$.*

PROOF. As in the proof of theorems IV.1.5 and IV.1.6, construct a sequence of infinite trees $T_j$, $j \in \mathbb{N}$, such that $\forall i < \mathrm{lh}(\tau)\,[\tau(i) \leq n_i]$ for all $\tau \in T_j$, and such that any path $g$ through $T_j$ gives rise to a point

$$x = \lim_i x_{i,g(i)} \in C_j.$$

Let $T = \oplus_{j\in\mathbb{N}} T_j$ be the interleaved tree, defined by putting $\tau \in T$ if and only if $\forall j\,[\tau_j \in T_j]$, where $\tau_j(i) = \tau((i, j))$ for all $(i, j) < \mathrm{lh}(\tau)$. We also require that $\tau(k) = 0$ for all $k < \mathrm{lh}(\tau)$ not of the form $(i, j)$. Then $T$ is a bounded tree, the bounding function $h$ being given by $h((i, j)) = n_i + 1$, $h(k) = 1$ for all $k$ not of the form $(i, j)$. In order to show that $T$ is infinite, we prove that for all $n$ there exists $\tau \in T$ of length $n$ such that

$$\forall j\,\forall m\,(m \geq \mathrm{lh}(\tau_j) \to \tau_j \text{ has an extension of length } m \text{ in } T_j).$$

This $\Pi^0_1$ statement is easily proved by $\Pi^0_1$ induction on $n$, using the fact that each of the $T_j$'s is infinite.

Since $T$ is infinite and bounded, it follows by bounded König's lemma in $\mathsf{WKL}_0$ (lemma IV.1.4) that $T$ has an infinite path $f$. Then for each $j$ we have a path $f_j$ through $T_j$ given by $f_j(i) = f((i, j))$. Thus $x_j = \lim_i x_{i,f_j(i)}$ belongs to $C_j$. This completes the proof. □

**Notes for §IV.1.** The formal system $\mathsf{WKL}_0$ was first defined by Friedman [69]. Theorem IV.1.2 was announced by Friedman [69]. Theorem IV.1.5 and its proof are taken from Brown's thesis [24]. Theorem IV.1.7 is from Blass/Hirst/Simpson [21]. Theorem IV.1.8 is due to Simpson, unpublished.

## IV.2. Properties of Continuous Functions

In this section we shall show that $\mathsf{WKL}_0$ is just strong enough to prove several basic results concerning continuous functions of a real variable. We shall also generalize some of these results so as to apply to continuous functions on compact metric spaces.

DEFINITION IV.2.1 (modulus of uniform continuity). The following definition is made in $\mathsf{RCA}_0$. Let $\widehat{A}$ and $\widehat{B}$ be complete separable metric spaces, and let $F$ be a continuous function from $\widehat{A}$ into $\widehat{B}$ (see definition II.6.1). A *modulus of uniform continuity* for $F$ is a function $h\colon \mathbb{N} \to \mathbb{N}$ such that for all $n \in \mathbb{N}$ and all $x$ and $y$ in $\widehat{A}$, if $F(x)$ and $F(y)$ are defined and $d(x, y) < 2^{-h(n)}$, then $d(F(x), F(y)) < 2^{-n}$.

THEOREM IV.2.2 (properties of continuous functions). *The following is provable in* $\mathsf{WKL}_0$. *Let $X = \widehat{A}$ be a compact metric space. Let $C$ be a closed set in $X$, and let $F$ be a continuous function from $C$ into a complete separable metric space $Y = \widehat{B}$. Then $F$ has a modulus of uniform continuity on $C$. If in addition $X = C$ and $Y = \mathbb{R}$, then $F$ attains a maximum value.*

PROOF. We reason in $\mathsf{WKL}_0$. Let $\varphi(n, a, r)$ be a $\Sigma^0_1$ formula which says that $a \in A$, $r \in \mathbb{Q}^+$, and $\exists b\, \exists s\, ((a, 2r)F(b, s) \wedge s < 2^{-n-1})$. Since $F(x)$ is defined for all $x \in C$, we can easily show that for all $x \in C$ and $n \in \mathbb{N}$ there exist $a$, $r$ such that $\varphi(n, a, r)$ holds and $d(x, a) < r$. By lemma II.3.7, let $\langle (a_{ni}, r_{ni})\colon i, n \in \mathbb{N}\rangle$ be such that

$$\forall n\, \forall a\, \forall r\, (\varphi(n, a, r) \leftrightarrow \exists i\, (a, r) = (a_{ni}, r_{ni})).$$

Thus $\langle \langle \mathrm{B}(a_{ni}, r_{ni})\colon i \in \mathbb{N}\rangle\colon n \in \mathbb{N}\rangle$ is a sequence of open coverings of $C$. By theorem IV.1.6, let $\langle \langle \mathrm{B}(a_{ni}, r_{ni})\colon i \le k_n\rangle\colon n \in \mathbb{N}\rangle$ be a sequence of finite subcoverings. Define $h\colon \mathbb{N} \to \mathbb{N}$ by putting $h(n) =$ the least $j$ such that $2^{-j} < \min\{r_{ni}\colon i \le k_n\}$. If $x, y \in C$ and $d(x, y) < 2^{-h(n)}$, let $i \le k_n$ be such that $x \in \mathrm{B}(a_{ni}, r_{ni})$. Then $x, y \in \mathrm{B}(a_{ni}, 2r_{ni})$, so $F(x)$, $F(y)$ both belong to the closure of $\mathrm{B}(b, s)$ where $s < 2^{-n-1}$. Hence $d(F(x), F(y)) < 2^{-n}$. This proves that $h$ is a modulus of uniform continuity for $F$ on $C$.

Assume now that $X = C$ and $Y = \mathbb{R}$. It is straightforward to show that

$$\alpha = \lim_n \max\{F(a_{ni})\colon i \le k_n\}$$

exists and is the least upper bound of all $F(x)$, $x \in X$. It remains to show that $F(x) = \alpha$ for some $x \in X$. Suppose not. Let $\varphi(a, r, b, s)$ be a $\Sigma^0_1$ formula saying that $(a, r)F(b, s)$ holds and $b + s < \alpha$. By lemma II.3.7, there is a sequence $\langle (a_i, r_i, b_i, s_i) : i \in \mathbb{N} \rangle$ such that

$$\forall a, r, b, s \, (\varphi(a, r, b, s) \leftrightarrow \exists i \, (a, r, b, s) = (a_i, r_i, b_i, s_i)).$$

Since $F(x) < \alpha$ for all $x \in X$, the sequence $\langle \mathrm{B}(a_i, r_i) : i \in \mathbb{N} \rangle$ is an open covering of $X$. By theorem IV.1.5, there is a finite subcovering $\langle \mathrm{B}(a_i, r_i) : i \leq k \rangle$. Put $\beta = \max\{b_i + s_i : i \leq k\}$. Then $\beta < \alpha$ and for all $x \in \widehat{A}$ we have $F(x) \leq \beta$, contradicting the definition of $\alpha$.

This completes the proof of theorem IV.2.2. □

We now turn to Reverse Mathematics. We show that weak König's lemma is needed to prove some basic properties of continuous functions. Among other things, the following theorem says that $\mathsf{WKL}_0$ is equivalent (over $\mathsf{RCA}_0$) to the assertion that every continuous, real-valued function on the closed unit interval attains a maximum value.

A continuous function $F$ is said to be *uniformly continuous* if for all $\epsilon > 0$ there exists $\delta > 0$ such that if $d(x_1, x_2) < \delta$ and $F(x_1)$ and $F(x_2)$ are defined, then $d(F(x_1), F(x_2)) < \epsilon$.

THEOREM IV.2.3 (reversals). *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Weak König's lemma.*
2. *Every continuous function on the closed interval* $0 \leq x \leq 1$ *is uniformly continuous.*
3. *Every continuous function on* $0 \leq x \leq 1$ *is bounded.*
4. *Every bounded, uniformly continuous function on* $0 \leq x \leq 1$ *has a supremum.*
5. *Every bounded, uniformly continuous function on* $0 \leq x \leq 1$ *which has a supremum, attains it.*

PROOF. The fact that $\mathsf{WKL}_0$ proves assertions 2, 3, 4, and 5 follows immediately as a special case of theorem IV.2.2. (These are essentially the standard proofs based on the Heine/Borel theorem.)

It remains to show that $\neg\mathsf{WKL}_0$ implies $\neg 2$, $\neg 3$, $\neg 4$, $\neg 5$. We reason in $\mathsf{RCA}_0$. Assume $\neg\mathsf{WKL}_0$ and let $T \subseteq 2^{<\mathbb{N}}$ be an infinite tree with no path. Let $C$, $a_s$, $b_s$, and $\widetilde{T}$ be as in the proof of theorem IV.1.2. Since $T$ is a tree, the closed intervals

$$a_u \leq x \leq b_u, \qquad u \in \widetilde{T} \tag{10}$$

are pairwise disjoint, and since $T$ has no paths, they cover $C$. Thus any element of $0 \leq x \leq 1$ which does not belong to (10) must lie in an open interval $b_v < x < a_w$, $v \in \widetilde{T}$, $w \in \widetilde{T}$, which is disjoint from (10).

We shall now construct a counterexample to 2, i.e., a continuous real-valued function $\phi(x)$, $0 \leq x \leq 1$, which is not uniformly continuous. If $a_u \leq x \leq b_u$ for some $u \in \widetilde{T}$, define $\phi(x) = \mathrm{lh}(u)$. Otherwise define $\phi(x)$ by piecewise linearity, i.e.,

$$\phi(x) = \phi(b_v) + \frac{x - b_v}{a_w - b_v}(\phi(a_w) - \phi(b_v))$$

on each open interval $b_v < x < a_w$, $v \in \widetilde{T}$, $w \in \widetilde{T}$ which is disjoint from (10). The corresponding continuous function code $\Phi$ can be constructed by the same method as in the proof of theorem II.6.5. Since $\widetilde{T}$ is infinite, $\phi(x)$ is unbounded on $0 \leq x \leq 1$ and hence not uniformly continuous there. Thus $\phi_2(x) = \phi(x)$ is a counterexample to both 2 and 3.

Our counterexamples to 4 and 5 will be similar. Since $\mathsf{WKL}_0$ fails, it follows by theorem III.7.2 that $\mathsf{ACA}_0$ fails. Hence by theorem III.2.2 there exists a bounded increasing sequence of rational numbers $c_0 < c_1 < \cdots < c_n < \cdots < 2$ which has no least upper bound. Define a continuous real-valued function $\phi_4(x)$, $0 \leq x \leq 1$, as follows. If $a_u \leq x \leq b_u$, $u \in \widetilde{T}$, put $\phi_4(x) = c_{\mathrm{lh}(u)}$, otherwise define $\phi_4(x)$ by piecewise linearity as before. Thus $\sup\{\phi_4(x) \colon 0 \leq x \leq 1\} = \sup\{c_n \colon n \in \mathbb{N}\}$ does not exist although $\phi_4(x)$ is uniformly continuous and $0 < \phi_4(x) < 2$ for all $x$, $0 \leq x \leq 1$. Thus $\phi_4$ is a counterexample to 4.

Finally define $\phi_5(x)$, $0 \leq x \leq 1$, as follows. If $a_u \leq x \leq b_u$, $u \in \widetilde{T}$, put $\phi_5(x) = 1 - 2^{-\mathrm{lh}(u)}$, otherwise define $\phi_5(x)$ by piecewise linearity as before. Then $\phi_5$ is uniformly continuous and, since $\widetilde{T}$ is infinite, $\sup\{\phi_5(x) \colon 0 \leq x \leq 1\} = 1$. However, this supremum is clearly never attained. Thus we have a counterexample to 5.

This completes the proof of theorem IV.2.3. □

We shall now discuss the Weierstraß polynomial approximation theorem.

LEMMA IV.2.4 (Weierstraß approximation theorem). *The following is provable in* $\mathsf{RCA}_0$. *Let* $\phi(x)$ *be a continuous real-valued function defined on* $0 \leq x \leq 1$.

1. *If* $\phi(x)$ *is uniformly continuous, then for each* $\epsilon > 0$ *there exists a polynomial* $f(x) \in \mathbb{Q}[x]$ *such that* $|\phi(x) - f(x)| < \epsilon$ *for all* $x$, $0 \leq x \leq 1$.
2. *If* $\phi(x)$ *possesses a modulus of uniform continuity, then there exists a sequence of polynomials* $\langle f_n(x) \colon n \in \mathbb{N}\rangle$, $f_n(x) \in \mathbb{Q}[x]$, *such that* $|\phi(x) - f_n(x)| < 2^{-n}$ *for all* $n \in \mathbb{N}$ *and* $0 \leq x \leq 1$.

PROOF. Straightforward imitation of the usual "constructive" proof of the Weierstraß theorem. (For references, see the notes at the end of this section.) □

THEOREM IV.2.5. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Weak König's lemma.*
2. *For every continuous real-valued function* $\phi(x)$, $0 \leq x \leq 1$, *there exists a polynomial* $f(x)$ *such that* $|\phi(x) - f(x)| < 1$.
3. *For every continuous real-valued function* $\phi(x)$, $0 \leq x \leq 1$, *there exists a sequence of polynomials* $\langle f_n(x) : n \in \mathbb{N} \rangle$, $f_n(x) \in \mathbb{Q}[x]$, *such that* $|\phi(x) - f_n(x)| < 2^{-n}$ *for all* $n \in \mathbb{N}$ *and* $0 \leq x \leq 1$.

PROOF. Immediate from theorem IV.2.3 and lemma IV.2.4, since every polynomial $f(x)$ is bounded over $0 \leq x \leq 1$. □

Next we turn to the Riemann integral.

LEMMA IV.2.6 (Riemann integral). *The following is provable in* $\mathsf{RCA}_0$. *Let* $\phi(x)$ *be a continuous real-valued function on the closed bounded interval* $a \leq x \leq b$. *Assume in addition that* $\phi(x)$ *possesses a modulus of uniform continuity. Then the Riemann integral*

$$\int_a^b \phi(x)\,dx = \lim \sum_{i=1}^{n} \phi(x_i)\Delta x_i$$

*exists.* (*Here the limit is taken over all partitions* $a = a_0 < a_1 < \cdots < a_n = b$ *and* $a_i \leq x_i \leq a_{i+1}$, $\Delta x_i = a_{i+1} - a_i$, *as* $\max \Delta x_i$ *approaches* 0.) *Furthermore* $\int_a^x \phi(\xi)\,d\xi$ *is continuously differentiable on* $a \leq x \leq b$ *and its derivative is* $\phi(x)$.

PROOF. Straightforward adaptation of the usual argument, which employs a modulus of uniform continuity. □

THEOREM IV.2.7. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Weak König's lemma.*
2. *For every continuous function* $\phi(x)$ *on a closed bounded interval* $a \leq x \leq b$, *the Riemann integral* $\int_a^b \phi(x)\,dx$ *exists and is finite.*

PROOF. The implication from 1 to 2 is immediate from theorem IV.2.2 and lemma IV.2.6. For the converse, assume that $\mathsf{WKL}_0$ fails and let $T \subseteq 2^{<\mathbb{N}}$ be an infinite tree with no path. Let $a_s$, $b_s$, and $\widetilde{T}$ be as in the proof of theorem IV.2.3. Define a continuous function $\phi(x)$, $0 \leq x \leq 1$ as follows. If $a_u \leq x \leq b_u$ for some $u \in \widetilde{T}$, define $\phi(x) = 3^{\mathrm{lh}(u)} = |a_u - b_u|^{-1}$. Otherwise define $\phi(x)$ by piecewise linearity as in the proof of theorem IV.2.3. Since $\widetilde{T}$ is infinite, the Riemann integral $\int_0^1 \phi(x)\,dx$ would have to be infinite. Thus $\phi(x)$ is a counterexample to 2. This completes the proof. □

REMARK IV.2.8 (Bishop-style constructivism). In lemmas IV.2.4 and IV.2.6 we needed to assume a modulus of uniform continuity, because in general its existence is not provable in $\mathsf{RCA}_0$. However, it is interesting to note that "any continuous function which arises in practice" can be proved

in $\mathsf{RCA}_0$ to have a modulus of uniform continuity on any closed bounded subset of its domain. For instance, theorems II.6.2 through II.6.5 can be extended in this way. Thus lemmas IV.2.4 and IV.2.6 apply to "any continuous function which arises in practice." (We speak only of partial continuous functions from $\mathbb{R}^k$ into $\mathbb{R}$.)

This situation has prompted some authors, for example Bishop/Bridges [20, page 38], to build a modulus of uniform continuity into their definitions of continuous function. Such a procedure may be appropriate for Bishop since his goal is to replace ordinary mathematical theorems by their "constructive" counterparts. However, as explained in chapter I, our goal is quite different. Namely, we seek to draw out the set existence assumptions which are implicit in the ordinary mathematical theorems *as they stand*. (In particular, we have examined from this viewpoint the theorem that every continuous real-valued function on $0 \leq x \leq 1$ is uniformly continuous. See theorem IV.2.3 above.) Thus Bishop's procedure would not be appropriate for us.

EXERCISE IV.2.9. Show that $\mathsf{WKL}_0$ is equivalent over $\mathsf{RCA}_0$ to the assertion that every uniformly continuous real-valued function on the closed unit interval $0 \leq x \leq 1$ has a modulus of uniform continuity.

EXERCISE IV.2.10. Show that $\mathsf{WKL}_0$ is equivalent over $\mathsf{RCA}_0$ to the following assertion. Let $f$ be a continuous real-valued function on a nonempty closed set $C$ in a compact metric space. If $\alpha = \sup_{x \in C} f(x)$ exists, then $f(x_0) = \alpha$ for some $x_0 \in C$.

EXERCISE IV.2.11. Show that $\mathsf{ACA}_0$ is equivalent over $\mathsf{RCA}_0$ to each of the following assertions.

1. Every continuous real-valued function on a nonempty closed set in a compact metric space attains a maximum value.
2. Let $f$ be a continuous real-valued function on a nonempty closed set $C$ in the unit interval $0 \leq x \leq 1$. Then $\sup_{x \in C} f(x)$ exists.
3. For each nonempty closed set $C$ in the unit interval, $\sup C$ exists.

EXERCISE IV.2.12 (uniform intermediate value theorem). Show that $\mathsf{WKL}_0$ is equivalent over $\mathsf{RCA}_0$ to each of the following assertions.

1. If $\phi_n$, $n \in \mathbb{N}$, is a sequence of continuous real-valued functions on the closed unit interval $0 \leq x \leq 1$, then there exists a sequence of real numbers $x_n$, $n \in \mathbb{N}$, $0 \leq x_n \leq 1$, such that $\forall n\, (\phi_n(0) \leq 0 \leq \phi_n(1) \to \phi_n(x_n) = 0)$.
2. If $\phi_n$, $n \in \mathbb{N}$, is a sequence of continuous real-valued functions on $0 \leq x \leq 1$ such that $\forall n\, (\phi_n(0) \leq 0 \leq \phi_n(1) \wedge \phi_n$ is monotone increasing), then there exists a sequence of real numbers $x_n$, $n \in \mathbb{N}$, $0 \leq x_n \leq 1$, such that $\forall n\, \phi_n(x_n) = 0$.

(Compare theorem II.6.6.)

We end this section with some additional exercises indicating an $\mathsf{RCA}_0$ rendition of some functional analysis and measure theory over compact metric spaces.

EXERCISE IV.2.13 (the Banach space $\mathrm{C}(X)$). Within $\mathsf{RCA}_0$, let $X$ be a compact metric space. Show that there exists a separable Banach space $\mathrm{C}(X)$ whose points are in canonical one-to-one correspondence with continuous real-valued functions $\phi\colon X \to \mathbb{R}$ equipped with a modulus of uniform continuity. Moreover, the norm on $\mathrm{C}(X)$ corresponds to the sup norm $\|\phi\| = \sup_{x\in X} |\phi(x)|$. (Note: We are using the $\mathsf{RCA}_0$ notions of separable Banach space theory, as introduced in §II.10. See also lemma IV.2.4 and example II.10.3.)

Hint: The construction of $\mathrm{C}(X)$ within $\mathsf{RCA}_0$ is as follows. Let $X = \widehat{A}$ and let $d$ be the metric on $X$. Put $B = A \times \mathbb{Q}^+ \times \mathbb{Q}^+$. For $b = (a, r, s) \in B$ define a continuous function

$$\phi_b\colon X \to \mathbb{R} \text{ by } \phi_b(x) = \max(0, \min(s, 2s(r - d(a, x))/r)).$$

Put

$$C = \mathbb{Q} \times \{F\colon F \text{ is a finite nonempty subset of } B\}.$$

For $c = (q, F) \in C$ define a continuous function $\phi_c\colon X \to \mathbb{R}$ by $\phi_c(x) = q + \max\{\phi_b(x)\colon b \in F\}$. Finally $\mathrm{C}(X) = \widehat{C}$ under the sup norm given by $\|c\| = \|\phi_c\| = \sup_{x\in X} |\phi_c(x)|$.

DEFINITION IV.2.14 (Borel measures). Within $\mathsf{RCA}_0$, let $X$ be a compact metric space. A *Borel measure* on $X$ is defined to be a bounded linear functional $\mu\colon \mathrm{C}(X) \to \mathbb{R}$ such that $\mu(\phi) \geq 0$ for all $\phi \geq 0$ in $\mathrm{C}(X)$. By normalizing, we may assume that $\mu(1) = 1$.

EXERCISE IV.2.15 (the Banach spaces $\mathrm{L}_p(X, \mu)$, $1 \leq p < \infty$). Within $\mathsf{RCA}_0$, let $X$ be a compact metric space. Show that any Borel measure $\mu$ on $X$ gives rise to separable Banach spaces $\mathrm{L}_p(X, \mu)$, $1 \leq p < \infty$. Namely, if $\mathrm{C}(X) = \widehat{C}$ under the sup norm as in exercise IV.2.13, then $\mathrm{L}_p(X, \mu) = \widehat{C}$ under the $\mathrm{L}_p$-norm, $\|\phi\|_p = \mu(|\phi|^p)^{1/p}$.

EXAMPLE IV.2.16. Examples illustrating exercises IV.2.13 and IV.2.15 are $\mathrm{C}[0, 1]$ and $\mathrm{L}_p[0, 1] = \mathrm{L}_p([0, 1], \mu)$, $1 \leq p < \infty$, where $\mu\colon \mathrm{C}[0, 1] \to \mathbb{R}$ is the Riemann integral, $\mu(\phi) = \int_0^1 \phi(x)\, dx$. See also lemma IV.2.4 and examples II.10.3 and II.10.4. See also the notes at the end of this section.

DEFINITION IV.2.17 (located sets). Within $\mathsf{RCA}_0$, let $X$ be a complete separable metric space. A nonempty closed set $K \subseteq X$ is said to be *located* if the distance function

$$d(x, K) = \inf\{d(x, y)\colon y \in K\}$$

is a continuous real-valued function on $X$.

EXERCISE IV.2.18 (Hausdorff metric). Within $\mathsf{RCA}_0$, let $X$ be a compact metric space. Show that there exists a compact metric space $\mathrm{K}(X) \subseteq \mathrm{C}(X)$ whose points are in one-to-one correspondence with the nonempty closed located sets $K \subseteq X$. Furthermore, the metric on $\mathrm{K}(X)$ corresponds to the Hausdorff metric

$$d_{\mathrm{H}}(K_1, K_2) = \sup\{d(x_1, K_2), d(x_2, K_1) \colon x_1 \in K_1, x_2 \in K_2\}$$

or equivalently

$$d_{\mathrm{H}}(K_1, K_2) = \sup_{x \in X} |d(x, K_1) - d(x, K_2)|.$$

Hint: The construction of $\mathrm{K}(X)$ within $\mathsf{RCA}_0$ is as follows. Let $X = \widehat{A}$ and let $d$ be the metric on $X$. Put

$$A^* = \{F \colon F \text{ is a finite nonempty subset of } A\}.$$

Then $\mathrm{K}(X) = \widehat{A^*}$ under the metric $d^*$ given by

$$d^*(F_1, F_2) = \sup_{x \in X} |d(x, F_1) - d(x, F_2)|.$$

**Notes for §IV.2.** Theorem IV.2.3 is due to Simpson (unpublished, but see [243]). Theorem IV.2.2 is taken from Brown's thesis [24]. The results on polynomial approximation and the Riemann integral within $\mathsf{RCA}_0$ and $\mathsf{WKL}_0$ are due to Simpson, unpublished. An $\mathsf{RCA}_0$ version of $\mathrm{C}(X)$ similar to that of exercise IV.2.13 has been given by Brown [24, §III.E], who also proved an $\mathsf{RCA}_0$ version of the Stone/Weierstraß theorem. Bishop-style constructive versions of the Weierstraß polynomial approximation theorem and the Stone/Weierstraß theorem are in Bishop/Bridges [20, page 106]. Regarding exercise IV.2.15, note that measure theory in subsystems of $\mathsf{Z}_2$ has been studied by Yu/Simpson [280] and Brown/Giusto/Simpson [26]; see also Yu [275, 276, 277, 278, 279], Simpson [248], and section X.1 below. The results of exercise IV.2.18 on located sets and $\mathrm{K}(X)$ in $\mathsf{RCA}_0$ are from Giusto/Simpson [93].

## IV.3. The Gödel Completeness Theorem

In the previous section we showed that weak König's lemma is provably equivalent over $\mathsf{RCA}_0$ to several basic theorems on continuous functions of a real variable. We now show that weak König's lemma is also provably equivalent to several basic theorems of mathematical logic. We build on the results of §II.8.

DEFINITION IV.3.1. The following definition is made in $\mathsf{RCA}_0$. As in §II.8 we assume a fixed countable language $L$. Let $X$ be a countable set of sentences. A *completion* of $X$ is a countable set of sentences $X^* \supseteq X$ such that $X^*$ is consistent, complete, and closed under logical consequence.

LEMMA IV.3.2. *The following is provable in* $\mathsf{RCA}_0$. *Let $X$ be a countable set of sentences. There exists a tree $T = T_X \subseteq 2^{<\mathbb{N}}$ such that the paths through $T_X$ are just the characteristic functions of completions of $X$. Furthermore $T_X$ is infinite if and only if $X$ is consistent.*

PROOF. Put $t \in T$ if and only if $\forall \sigma < \mathrm{lh}(t)\,[t(\sigma) = 1 \to \sigma \in \mathrm{Snt}]$ and $\forall \sigma < \mathrm{lh}(t)\,[\sigma \in X \to t(\sigma) = 1]$ and $\forall p < \mathrm{lh}(t)\,[$if $p$ is a proof and $\forall i < \mathrm{lh}(p)\,(p(i)$ is a nonlogical axiom of $p \to t(p(i)) = 1)$ then $\forall i < \mathrm{lh}(p)\,(p(i) \in \mathrm{Snt} \to t(p(i)) = 1)]$ and $\forall \sigma < \mathrm{lh}(t)\,\forall \tau < \mathrm{lh}(t)\,[(\sigma \in \mathrm{Snt} \wedge \tau = \neg\sigma) \to t(\sigma) = 1 - t(\tau)]$. $T$ exists by $\Sigma^0_0$ comprehension and clearly $T$ has the desired properties. □

THEOREM IV.3.3. *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Weak König's lemma.*
2. Lindenbaum's lemma: *every countable consistent set of sentences has a completion.*
3. Gödel's completeness theorem: *every countable consistent set $X$ of sentences has a model, i.e., there exists a countable model $M$ such that $\forall \sigma\,(\sigma \in X \to M(\sigma) = 1)$.*
4. Gödel's compactness theorem: *if each finite subset of $X$ has a model then $X$ has a model.*
5. *The completeness theorem for propositional logic with countably many atoms.*
6. *The compactness theorem for propositional logic with countably many atoms.*

PROOF. We reason in $\mathsf{RCA}_0$. The implication $1 \to 2$ is immediate from the previous lemma. The implications $3 \to 4$, $4 \to 6$, $3 \to 5$, $5 \to 6$ are straightforward. It remains to prove $2 \to 3$ and $6 \to 1$.

Let $X$ be a countable consistent set of sentences. Let $C$ be an infinite set of new constant symbols, and let $\langle \underline{c}_n : n \in \mathbb{N} \rangle$ be a one-to-one enumeration of $C$. Let $\Phi$ be the set of all formulas $\varphi(x)$ with one free variable $x$ in the expanded language $L_1 = L \cup C$, and let $\langle \varphi_n(x) : n \in \mathbb{N} \rangle$ be an enumeration of $\Phi$. We may safely assume that $\underline{c}_n$ does not occur in $\varphi_i(x)$, $i \leq n$. Form Henkin sentences

$$\eta_n \equiv (\exists x\, \varphi_n(x)) \to \varphi_n(\underline{c}_n)$$

and let $X_1 = X \cup \{\eta_n : n \in \mathbb{N}\}$. The usual syntactic argument shows that $X_1$ is consistent, so by Lindenbaum's lemma let $X_1^*$ be a completion of $X_1$. A countable model $M$ of $X_1$ can be read off as in the proof of theorem II.8.4. This proves $2 \to 3$.

Now consider propositional logic with countably many atomic formulas $\langle a_n : n \in \mathbb{N} \rangle$. A set $X$ of formulas in this language is said to be *satisfiable* if and only if there exists a *model* of $X$, i.e., a function $f : \mathbb{N} \to \{0, 1\}$ such

that each formula of $X$ is true under the truth assignment

$$a_n \mapsto \begin{cases} \text{true} & \text{if } f(n) = 1, \\ \text{false} & \text{if } f(n) = 0. \end{cases}$$

The *compactness theorem* for propositional logic asserts that if each finite subset of $X$ is satisfiable then $X$ is satisfiable. We want to prove weak König's lemma from the compactness theorem.

Let $T \subseteq 2^{<\mathbb{N}}$ be an infinite tree. For each $n \in \mathbb{N}$ form a propositional formula

$$\sigma_n = \bigvee \{ \bigwedge \{ a_i^{s(i)} : i < n \} : s \in T, \mathrm{lh}(s) = n \}$$

where $a_i^1 = a_i$, $a_i^0 = \neg a_i$. Since $T$ contains sequences of length $n$, $\sigma_n$ is satisfiable. Also $\sigma_{n+1} \to \sigma_n$ is a tautology. Hence for each $n$, $\{\sigma_0, \sigma_1, \ldots, \sigma_n\}$ is satisfiable. From the compactness theorem it follows that $\{\sigma_n : n \in \mathbb{N}\}$ is satisfiable. Let $f : \mathbb{N} \to \{0,1\}$ be a model of $\{\sigma_n : n \in \mathbb{N}\}$. Then clearly $f$ is a path through $T$. This completes the proof of $6 \to 1$ and of theorem IV.3.3. □

**Notes for §IV.3.** The material in this section is due to Simpson, unpublished. Lemma IV.3.2 is inspired by Jockusch/Soare [134].

## IV.4. Formally Real Fields

A famous result of Artin and Schreier (see van der Waerden [270]) asserts that every formally real field is orderable. (This result was an essential ingredient in the Artin/Schreier solution of Hilbert's 17th problem; see [23].) The purpose of this section is to show that $\mathsf{WKL}_0$ is just strong enough to prove the Artin/Schreier result for countable fields.

Definition IV.4.1 (formally real fields). Within $\mathsf{RCA}_0$, let $K$ be a countable field. We say that $K$ is *formally real* if $-1$ is not a sum of squares in $K$. An equivalent condition is that $K$ does not contain a sequence of elements $\langle c_0, c_1, \ldots, c_n \rangle$, $c_i \neq 0$, $n \in \mathbb{N}$, such that $\sum_{i=0}^{n} c_i^2 = 0$.

Definition IV.4.2 (orderable fields). Within $\mathsf{RCA}_0$, a countable field $K$ is said to be *orderable* if there exists a binary relation $<_K$ on $K$ which makes $K$ into an ordered field. An equivalent condition is the existence of a "positive cone" $P \subseteq K$ such that $0 \notin P$ and $\forall a\, \forall b\, ((a \in P \wedge b \in P) \to (a + b \in P \wedge a \cdot b \in P))$ and $\forall a\, ((a \in K \wedge a \neq 0) \to (a \in P \leftrightarrow -a \notin P))$.

Lemma IV.4.3. $\mathsf{WKL}_0$ *proves that every countable, formally real field is orderable.*

Proof. We reason in $\mathsf{WKL}_0$. Let $K$ be countable, formally real field. Let $\langle a_i : i \in \mathbb{N} \rangle$ be an enumeration of the nonzero elements of $K$. For

each $t \in 2^{<\mathbb{N}}$ and $i < \mathrm{lh}(t)$ put

$$t_i = \begin{cases} 1 & \text{if } t(i) = 1, \\ -1 & \text{if } t(i) = 0. \end{cases}$$

Let $T$ be the set of all $t \in 2^{<\mathbb{N}}$ such that for all $i, j, k < \mathrm{lh}(t)$,

(i) $a_i + a_j = a_k$ and $t_i = t_j = 1$ imply $t_k = 1$ ;
(ii) $a_i \cdot a_j = a_k$ and $t_i = t_j = 1$ imply $t_k = 1$;
(iii) $a_i = -a_j$ implies $t_i = -t_j$.

Clearly $T$ is a tree. Assume for a contradiction that $T$ is finite. Let $n \in \mathbb{N}$ be such that $T$ contains no $t \in 2^{<\mathbb{N}}$ of length $n$. Then for each $t \in 2^{<\mathbb{N}}$ of length $n$ there exist $i, j, k < n$ such that either $t_i a_i + t_j a_j + t_k a_k = 0$ or $t_i a_i t_j a_j + t_k a_k = 0$ or $t_i a_i + t_j a_j = 0$. Hence $f_t = 0$ where

$$f_t = \prod_{i,j,k<n} (t_i a_i + t_j a_j + t_k a_k)^2 (t_i a_i t_j a_j + t_k a_k)^2 (t_i a_i + t_j a_j)^2.$$

Now expand $f_t$ as a sum of monomial terms of the form $\alpha_t = \prod_{i<n} t_i^{e_i} a_i^{e_i}$ where $e_i \in \mathbb{N}$. Note that if all of the $e_i$ are even, then $\alpha_t$ is a nonzero square, and furthermore there is at least one monomial $\alpha_t$ of this type. On the other hand, if some $e_i$ is odd, we have $\sum\{\alpha_t : \mathrm{lh}(t) = n\} = 0$ because each summand with $t_i = 1$ is cancelled by a corresponding summand with $t_i = -1$. Thus $\sum\{f_t : \mathrm{lh}(t) = n\} = 0$ leads to an expression of 0 as a nontrivial sum of squares, contradicting the assumption that $K$ is formally real. This proves that $T$ is infinite. By weak König's lemma let $g : \mathbb{N} \to \{0, 1\}$ be a path through $T$. Let $P$ be the set of all $a_i \in K$ such that $g(i) = 1$. Clearly $P$ is a positive cone for $K$ so $K$ is orderable. This completes the proof. □

In order to prove the converse of lemma IV.4.3, we shall need the following result which gives a useful equivalent characterization of weak König's lemma.

LEMMA IV.4.4 ($\mathsf{WKL}_0$ and $\Sigma^0_1$ separation). *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{WKL}_0$.
2. ($\Sigma^0_1$ separation) *Let* $\varphi_i(n)$, $i = 0, 1$ *be* $\Sigma^0_1$ *formulas in which* $X$ *does not occur freely. If* $\neg\exists n\,(\varphi_0(n) \wedge \varphi_1(n))$ *then*
$$\exists X\,\forall n\,((\varphi_0(n) \to n \in X) \wedge (\varphi_1(n) \to n \notin X)).$$
3. *If* $f, g : \mathbb{N} \to \mathbb{N}$ *are one-to-one with* $\forall m\,\forall n\, f(m) \neq g(n)$, *then*
$$\exists X\,\forall m\,(f(m) \in X \wedge g(m) \notin X).$$

PROOF. First assume $\mathsf{WKL}_0$ and let $\varphi_i(n)$, $i = 0, 1$, be $\Sigma^0_1$ with $\neg\exists n\,(\varphi_0(n) \wedge \varphi_1(n))$. Let $\varphi_i(n) \equiv \exists m\,\theta_i(m, n)$ where $\theta_i(m, n)$ is $\Sigma^0_0$. Let $T$ be the set of all $t \in 2^{<\mathbb{N}}$ such that

$$(\forall i < 2)\,(\forall m < \mathrm{lh}(t))\,(\forall n < \mathrm{lh}(t))\,(\theta_i(m, n) \to t(n) = 1 - i).$$

$T$ exists by $\Sigma^0_0$ comprehension. Clearly $T$ is an infinite tree. By weak König's lemma let $X$ be a set whose characteristic function is a path through $T$. Then clearly $X$ satisfies the conclusion of 2. This proves that 1 implies 2. The equivalence of 2 and 3 is immediate from lemma II.3.7.

It remains to prove that 2 implies 1. Assume 2 and let $T \subseteq 2^{<\mathbb{N}}$ be an infinite tree. Let $\theta(n,\sigma)$ be the $\Sigma^0_0$ formula $\exists\tau\,(\mathrm{lh}(\tau) = n \wedge \tau \in T \wedge \tau \supseteq \sigma)$. Let $\varphi(\sigma,i)$ be the $\Sigma^0_1$ formula $\exists n\,(\theta(n,\sigma^\frown\langle i\rangle) \wedge \neg\theta(n,\sigma^\frown\langle 1-i\rangle))$. Clearly $\neg\exists\sigma\,(\varphi(\sigma,0) \wedge \varphi(\sigma,1))$ so by the assumption 2 let $X$ be such that $\forall\sigma\,((\varphi(\sigma,0) \to \sigma \in X) \wedge (\varphi(\sigma,1) \to \sigma \notin X))$. Now define a sequence of sequences $\sigma_0 \subseteq \sigma_1 \subseteq \cdots \subseteq \sigma_k \subseteq \cdots$ in $2^{<\mathbb{N}}$ by $\sigma_0 =$ empty sequence, $\sigma_{k+1} = \sigma_k{}^\frown\langle 0\rangle$ if $\sigma_k \in X$, $\sigma_{k+1} = \sigma_k{}^\frown\langle 1\rangle$ if $\sigma_k \notin X$. Clearly $\mathrm{lh}(\sigma_k) = k$ for all $k$. We claim that $\theta(n,\sigma_k)$ holds for all $k$ and $n$ with $k \leq n$. Fix $n$. We prove the claim by induction on $k \leq n$. Trivially $\theta(n,\sigma_0)$ since $T$ is infinite. Assume inductively that $\theta(n,\sigma_k)$ holds for some $k < n$. Clearly either $\theta(n,\sigma_k{}^\frown\langle 0\rangle)$ or $\theta(n,\sigma_k{}^\frown\langle 1\rangle)$ must hold. If $\neg\theta(\sigma_k{}^\frown\langle 0\rangle)$ then we have $\varphi(\sigma_k,1)$, hence $\sigma_k \notin X$ so $\sigma_{k+1} = \sigma_k{}^\frown\langle 1\rangle$ whence $\theta(n,\sigma_{k+1})$. If $\neg\theta(\sigma_k{}^\frown\langle 1\rangle)$ then we have $\varphi(\sigma_k,0)$, hence $\sigma_k \in X$ so $\sigma_{k+1} = \sigma_k{}^\frown\langle 0\rangle$ whence $\theta(n,\sigma_{k+1})$. In any case $\theta(n,\sigma_{k+1})$ holds so our claim is proved. In particular we have $\theta(n,\sigma_n)$, i.e., $\sigma_n \in T$, for all $n$. so $f = \bigcup\{\sigma_n : n \in \mathbb{N}\}$ is a path through $T$. This proves weak König's lemma from 2. The proof of lemma IV.4.4 is complete. □

We now show that weak König's lemma is needed to prove the orderability of countable, formally real fields.

Theorem IV.4.5. *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{WKL}_0$.
2. *Every countable, formally real field is orderable.*
3. *Every countable, formally real field has a real closure.*

Proof. Assertions 2 and 3 are equivalent in view of theorem II.9.7. Lemma IV.4.3 shows that 1 implies 2. It remains to prove that 2 implies 1. Assume 2. Instead of proving weak König's lemma directly, we shall prove the equivalent statement IV.4.4.3. Let $f, g : \mathbb{N} \to \mathbb{N}$ be functions such that $\forall i\,\forall j\, f(i) \neq g(j)$. Let $\langle p_k : k \in \mathbb{N}\rangle$ be an enumeration of the rational primes, $p_0 = 2$, $p_1 = 3$, $p_2 = 5, \ldots$. By theorem II.9.7 let $\overline{\mathbb{Q}}$ be the real closure of the rational field $\mathbb{Q}$. For each $n \in \mathbb{N}$ let $K_n$ be the subfield of $\overline{\mathbb{Q}}(\sqrt{-1})$ generated by

$$\{\sqrt[4]{p_{f(i)}} : i < n\} \cup \left\{\sqrt{-\sqrt{p_{g(j)}}} : j < n\right\} \cup \{\sqrt{p_k} : k < n\}.$$

Because we lack $\Sigma^0_1$ comprehension we cannot form the subfield $\bigcup_{n\in\mathbb{N}} K_n$. However, we can apply lemma II.3.7 to find a field $K$ and an embedding $h : K \to \mathbb{Q}(\sqrt{-1})$ such that $\forall b\,(\exists n\,(b \in K_n) \leftrightarrow \exists a\,(h(a) = b))$.

Note that each $K_n$ is embeddable into $\overline{\mathbb{Q}}$ by taking $\sqrt{p_{f(i)}}$ to $\sqrt{p_{f(i)}}$ and $\sqrt{p_k}$ to $-\sqrt{p_k}$ whenever $k \neq f(i)$ for all $i < n$. Since $\overline{\mathbb{Q}}$ is an ordered field, it follows that each $K_n$ is formally real. Hence $K$ is formally real. Hence by 2, $K$ is orderable. Fix an ordering of $K$. Since $h^{-1}\sqrt{p_{f(i)}}$ has a square root in $K$ (namely $h^{-1}\sqrt[4]{p_{f(i)}}$), we must have $h^{-1}\sqrt{p_{f(i)}} > 0$. On the other hand, since $-h^{-1}\sqrt{p_{g(j)}}$ has a square root in $K$ (namely $h^{-1}\sqrt{-\sqrt{p_{g(j)}}}$), we must have $h^{-1}\sqrt{p_{g(j)}} < 0$. By $\Delta^0_1$ comprehension let $X$ be the set of all $k \in \mathbb{N}$ such that $h^{-1}\sqrt{p_k} > 0$. Then $\forall i\,(f(i) \in X)$ and $\forall j\,(g(j) \notin X)$. By lemma IV.4.4 this gives weak König's lemma. The proof of the theorem is complete. □

REMARK IV.4.6. $\mathsf{WKL}_0$ is also equivalent over $\mathsf{RCA}_0$ to the assertion that every countable torsion-free Abelian group is orderable. This result of Hatzikiriakou/Simpson [113] is related to a recursive counterexample of Downey/Kurtz [47]. Solomon [251] has obtained additional Reverse Mathematics results concerning orderability of countable groups.

REMARK IV.4.7. $\mathsf{WKL}_0$ is also equivalent over $\mathsf{RCA}_0$ to the theorem on extension of valuations for countable fields: Given a monomorphism of countable fields $h\colon K_1 \to K_2$ and a valuation ring $V_1$ of $K_1$, there exists a valuation ring $V_2$ of $K_2$ such that $V_1 = h^{-1}(V_2)$. This result is due to Hatzikiriakou/Simpson [112].

EXERCISE IV.4.8. Show that $\mathsf{RCA}_0$ proves $\Pi^0_1$ *separation*: For any $\Pi^0_1$ formulas $\psi_1(n)$ and $\psi_0(n)$ in which $Z$ does not occur freely, $\neg\exists n\,(\psi_1(n) \wedge \psi_0(n)) \to \exists Z\,\forall n\,((\psi_1(n) \to n \in Z) \wedge (\psi_0(n) \to n \notin Z))$. This is in contrast to lemma IV.4.4.

**Notes for §IV.4.** The main results of this section are from Friedman/Simpson/Smith [78]. A corollary of theorem IV.4.5 is that there exists a recursive, formally real field with no recursive ordering. This result is originally due to Ershov [54]. An improvement of Ershov's result due to Metakides/Nerode [187] states that for any recursive tree $T \subseteq 2^{<\mathbb{N}}$ there exists a recursive, formally real field $K$ such that the space of all orderings of $K$ is recursively homeomorphic to $[T]$, the closed set in $2^{\mathbb{N}}$ consisting of all paths through $T$.

## IV.5. Uniqueness of Algebraic Closure

In §II.9 we showed that $\mathsf{RCA}_0$ proves that every countable field has an algebraic closure. In this section we show that $\mathsf{WKL}_0$ is needed to prove that these algebraic closures are unique.

LEMMA IV.5.1 (uniqueness of algebraic closure). *It is provable in* $\mathsf{WKL}_0$ *that every countable field* $K$ *has a unique algebraic closure.* (*Uniqueness means that if* $h_i\colon K \to \widetilde{K}_i$, $i = 1, 2$ *are two algebraic closures of* $K$ *then there exists an isomorphism* $h\colon \widetilde{K}_1 \to \widetilde{K}_2$ *of* $\widetilde{K}_1$ *onto* $\widetilde{K}_2$ *such that* $h(h_1(a)) = h_2(a)$ *for all* $a \in K$.)

PROOF. Let $K$ be a countable field. The existence of an algebraic closure $h\colon K \to \widetilde{K}$ is provable in $\mathsf{RCA}_0$ (theorem II.9.4). For the uniqueness, let $h_i\colon K \to \widetilde{K}_i$, $i = 1, 2$ be two algebraic closures of $K$. Let $\langle a_i : i \in \mathbb{N}\rangle$ be an enumeration of the elements of $K$ and let $\langle b_i : i \in \mathbb{N}\rangle$ be an enumeration of the elements of $\widetilde{K}_1$. Let $\langle p_i(x)\colon i \in \mathbb{N}\rangle$ be a sequence of nonconstant polynomials $p_i(x) \in K[x]$ such that $h_1(p_i)(b_i) = 0$. (We do not demand that $p_i(x)$ be irreducible.) Let $T$ be the set of all $t \in \mathbb{N}^{<\mathbb{N}}$ such that $\forall i\,(i < \mathrm{lh}(t) \to t(i) \in \widetilde{K}_2)$ and for all $i, j, k < \mathrm{lh}(t)$

(i) $b_i + b_j = b_k$ implies $t(i) + t(j) = t(k)$;
(ii) $b_i \cdot b_j = b_k$ implies $t(i) \cdot t(j) = t(k)$;
(iii) $h_1(a_i) = b_j$ implies $h_2(a_i) = t(j)$;
(iv) $h_2(p_i)(t(i)) = 0$.

The idea is that $t \in T$ encodes a partial isomorphism of $\widetilde{K}_1$ onto $\widetilde{K}_2$ over $K$. Clearly $T$ is a subtree of $\mathbb{N}^{<\mathbb{N}}$. By considering finitely generated algebraic extensions of $K$, we can show that $T$ is infinite. (For details see Friedman/Simpson/Smith [78].) Also $T$ is a bounded tree since by (iv) we have $t(i) \le g(i) = \max\{c\colon c \in \widetilde{K}_2 \wedge h_2(p_i)(c) = 0\}$. Hence by bounded König's lemma in $\mathsf{WKL}_0$ (lemma IV.1.4), there exists a path $f$ through $T$. Define $h\colon \widetilde{K}_1 \to \widetilde{K}_2$ by $h(b_i) = f(i)$. Clearly $h$ is an isomorphism of $\widetilde{K}_1$ onto $\widetilde{K}_2$ and by (iii) we have $h(h_1(a_i)) = h_2(a_i)$ for all $a_i \in K$. This completes the proof. □

We now prove the converse.

THEOREM IV.5.2. *The following are equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{WKL}_0$.
2. *Every countable field has a unique algebraic closure.*

PROOF. Lemma IV.5.1 gives half of the theorem. For the other half, assume 2. Instead of proving weak König's lemma directly, we shall prove the equivalent statement IV.4.4.3. Let $f, g\colon \mathbb{N} \to \mathbb{N}$ be functions such that $\forall i\,\forall j\, f(i) \ne g(j)$. By theorem II.9.7 let $\overline{\mathbb{Q}}$ be the real closure of the rational field $\mathbb{Q}$. Let $\langle p_n : n \in \mathbb{N}\rangle$ be the enumeration of the rational primes in increasing order, i.e., $p_0 = 2$, $p_1 = 3$, $p_2 = 5, \ldots$. For each $n \in \mathbb{N}$ let $K_n$ be the subfield of $\overline{\mathbb{Q}}$ generated by

$$\{\sqrt{p_{f(i)}}\colon i < n\} \cup \{\sqrt{p_{g(j)}}\colon j < n\}.$$

By lemma II.3.7 let $K$ be a countable field and $h_1\colon K \to \overline{\mathbb{Q}}$ a monomorphism such that $\forall b\,(\exists n\,(b \in K_n) \leftrightarrow \exists a\,(h_1(a) = b))$. Define another monomorphism $h_2\colon K \to \overline{\mathbb{Q}}$ by putting $h_2(h_1^{-1}(\sqrt{p_{f(i)}})) = \sqrt{p_{f(i)}}$ and

$h_2(h_1^{-1}(\sqrt{p_{g(j)}})) = -\sqrt{p_{g(j)}}$. Thus $h_1, h_2 \colon K \to \overline{\mathbb{Q}}(\sqrt{-1})$ are two algebraic closures of $K$. By 2 there exists an automorphism $h \colon \overline{\mathbb{Q}}(\sqrt{-1}) \to \overline{\mathbb{Q}}(\sqrt{-1})$ such that $h(h_1(a)) = h_2(a)$ for all $a \in K$. Let $X$ be the set of all $m$ such that $h(\sqrt{p_m}) = \sqrt{p_m}$. Then

$$h(\sqrt{p_{f(i)}}) = h(h_1(h_1^{-1}(p_{f(i)}))) = h_2(h_1^{-1}(\sqrt{p_{f(i)}})) = \sqrt{p_{f(i)}}$$

and

$$h(\sqrt{p_{g(j)}}) = h(h_1(h_1^{-1}(p_{g(j)}))) = h_2(h_1^{-1}(\sqrt{p_{g(j)}})) = -\sqrt{p_{g(j)}}$$

so $f(i) \in X$ and $g(j) \notin X$. By lemma IV.4.4 this implies weak König's lemma. The proof of the theorem is complete. □

**Notes for §IV.5.** The results of this section are from Friedman/Simpson/Smith [78].

## IV.6. Prime Ideals in Countable Commutative Rings

In this section we show that $\mathsf{WKL}_0$ is just strong enough to accommodate the development of an important topic in commutative algebra.

DEFINITION IV.6.1 (prime ideals). Within $\mathsf{RCA}_0$, let $R$ be a countable commutative ring. A *prime ideal* of $R$ is a set $P \subseteq R$ such that $P$ is an ideal of $R$ (definition III.5.2) and $\forall a \, \forall b \, (a \cdot b \in P \to (a \in P \vee b \in P))$.

A basic theorem of commutative algebra asserts that every commutative ring has a prime ideal. The usual way to prove this theorem is to obtain a maximal ideal (by Zorn's lemma) and then to observe that maximal ideals are prime. This method cannot work in $\mathsf{WKL}_0$ since by theorem III.5.5 the existence of maximal ideals is not provable in $\mathsf{WKL}_0$. Nevertheless, we have:

LEMMA IV.6.2 (existence of prime ideals). *It is provable in* $\mathsf{WKL}_0$ *that every countable commutative ring possesses a prime ideal.*

PROOF. We reason in $\mathsf{WKL}_0$. Let $R$ be a countable commutative ring and let $\langle a_i : i \in \mathbb{N} \rangle$ be an enumeration of the elements of $R$. Use primitive recursion (theorem II.3.4) to define a sequence of (codes for) finite sets $X_s \subseteq R$, $s \in 2^{<\mathbb{N}}$, beginning with $X_{\langle\rangle} = \{0\}$. (Here $\langle\rangle$ denotes the empty sequence.) Let $s \in 2^{<\mathbb{N}}$ be given and suppose that $X_s$ has already been defined. Let

$$\mathrm{lh}(s) = 4 \cdot ((i, j), m) + k, \quad 0 \leq k < 4, \tag{11}$$

where $(i, j)$ denotes the pairing function (theorem II.2.2).

Case 1: $k = 0$. If $a_i \cdot a_j \in X_s$ put $X_{s^\frown\langle 0\rangle} = X_s \cup \{a_i\}$ and $X_{s^\frown\langle 1\rangle} = X_s \cup \{a_j\}$; otherwise put $X_{s^\frown\langle 0\rangle} = X_s$ and $X_{s^\frown\langle 1\rangle} = \emptyset$ = the empty set.

Case 2: $k = 1$. Put $X_{s^\frown\langle 0\rangle} = \emptyset$. If $a_i \in X_s$ and $a_j \in X_s$ put $X_{s^\frown\langle 1\rangle} = X_s \cup \{a_i + a_j\}$, otherwise $X_{s^\frown\langle 1\rangle} = X_s$.

Case 3: $k = 2$. Put $X_{s^\frown\langle 0\rangle} = \emptyset$. If $a_i \in X_s$ put $X_{s^\frown\langle 1\rangle} = X_s \cup \{a_i \cdot a_j\}$, otherwise $X_{s^\frown\langle 1\rangle} = X_s$.

Case 4: $k = 3$. Put $X_{s^\frown\langle 0\rangle} = \emptyset$. If $1 \in X_s$ put $X_{s^\frown\langle 1\rangle} = \emptyset$, otherwise $X_{s^\frown\langle 1\rangle} = X_s$.

If $\mathrm{lh}(s)$ is not as in (11), put $X_{s^\frown\langle 0\rangle} = \emptyset$ and $X_{s^\frown\langle 1\rangle} = X_s$. This completes the construction of $X_s$ for all $s \in 2^{<\mathbb{N}}$.

Let $S$ be the set of all $s \in 2^{<\mathbb{N}}$ such that $X_s \neq \emptyset$. Clearly $S$ is a tree.

We claim that for each $n \in \mathbb{N}$ there exists $s \in S$ of length $n$ such that $X_s$ does not generate $R$ as an $R$-module. For $n = 0$ the claim is trivial. If $n \equiv 1$, 2, or 3 mod 4 and the claim holds for $n$ then trivially it holds for $n + 1$. Suppose $n \equiv 0$ mod 4 and the claim holds for $n$. Let $s \in S$ be of length $n$ such that $X_s$ does not generate $R$ as an $R$-module. Let $n = 4 \cdot ((i, j), m)$. If $a_i \cdot a_j \notin X_s$ then trivially our claim holds for $n + 1$. If $a_i \cdot a_j \in X_s$ then we make a subclaim that $X_{s^\frown\langle 0\rangle} = X_s \cup \{a_i\}$ and $X_{s^\frown\langle 1\rangle} = X_s \cup \{a_j\}$ do not both generate $R$ as an $R$-module. If they did, we would have $1 = c + ra_i = d + sa_j$ where $r, s \in R$ and $c, d$ are finite linear combinations of elements of $X_s$ with coefficients from $R$. Then $1 = cd + csa_j + dra_i + rsa_ia_j$ so $X_s$ generates $R$ as a $R$-module, a contradiction. This proves the subclaim. Hence our claim holds for $n+1$. The claim for all $n \in \mathbb{N}$ now follows by $\Pi^0_1$ induction on $n$.

The above claim implies that $S$ is infinite. Hence by weak König's lemma $S$ has a path, call it $f$. If it were now possible to form the set of all $a \in R$ such that $\exists n\,(a \in X_{f[n]})$, then clearly this set would be a prime ideal of $R$ and the proof of lemma IV.6.2 would be complete. (Here $f[n]$ denotes the initial sequence of $f$ of length $n$.) Unfortunately, we cannot form this set because we lack $\Sigma^0_1$ comprehension. However, we can use bounded $\Sigma^0_1$ comprehension to finish the proof as follows.

We may safely assume that our enumeration $\langle a_i : i \in \mathbb{N}\rangle$ of $R$ is such that $a_0 = 0$ and $a_1 = 1$. Let $T$ be the set of all $t \in 2^{<\mathbb{N}}$ such that

(i) $0 < \mathrm{lh}(t)$ implies $t(0) = 0$;
(ii) $1 < \mathrm{lh}(t)$ implies $t(1) = 1$;
(iii) if $i, j, k < \mathrm{lh}(t)$ then
  (a) $t(i) = t(j) = 0$ and $a_i + a_j = a_k$ imply $t(k) = 0$;
  (b) $t(i) = 0$ and $a_i \cdot a_j = a_k$ imply $t(k) = 0$;
  (c) $t(i) = t(j) = 1$ and $a_i \cdot a_j = a_k$ imply $t(k) = 1$.

Clearly $T$ is a tree. We claim that $T$ is infinite. To see this, let $m \in \mathbb{N}$ be given. By bounded $\Sigma^0_1$ comprehension (theorem II.3.9) let $Y$ be the set of all $i < m$ such that $\exists n\,(a_i \in X_{f[n]})$. Define $t \in 2^{<\mathbb{N}}$, $\mathrm{lh}(t) = m$ by putting $t(i) = 0$ if $i \in Y$, $t(i) = 1$ if $i \notin Y$. Then clearly $t \in T$ and $\mathrm{lh}(t) = m$. This proves that $T$ is infinite. Hence by another application

of weak König's lemma there exists a path $g$ through $T$. Let $P$ be the set of all $a_i \in R$ such that $g(i) = 0$. Then clearly $P$ is a prime ideal of $R$.

This completes the proof of lemma IV.6.2. □

We now turn to the reversal. First, a definition:

DEFINITION IV.6.3 (radical ideals). Within $\mathsf{RCA}_0$, let $R$ be a countable commutative ring. A *radical ideal* of $R$ is an ideal $J \subseteq R$ (cf. definition III.5.2) such that $a^n \in J$ implies $a \in J$ for all $a \in R$, $n \in \mathbb{N}$.

Clearly every prime ideal of $R$ is a radical ideal of $R$.

THEOREM IV.6.4 (reversal). *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{WKL}_0$.
2. *Every countable commutative ring contains a prime ideal.*
3. *Every countable commutative ring contains a radical ideal.*

PROOF. The implication from 1 to 2 has already been proved as lemma IV.6.2. The implication from 2 to 3 is trivial. It remains to prove that 3 implies 1. We reason in $\mathsf{RCA}_0$. Assume 3. Instead of proving weak König's lemma directly, we shall prove the equivalent IV.4.4.3.

Let $f, g : \mathbb{N} \to \mathbb{N}$ be given with $\forall i \, \forall j \, (f(i) \neq g(j))$. Let $R_0 = \mathbb{Q}[\langle x_n : n \in \mathbb{N}\rangle]$ be the polynomial ring over rational field $\mathbb{Q}$ with countably many indeterminates $x_n$, $n \in \mathbb{N}$. Let $I \subseteq R_0$ be the ideal generated by the polynomials $x_{f(m)}^{m+1}$ and $x_{g(m)}^{m+1} - 1$, $m \in \mathbb{N}$. To see that $I$ exists, note that any given $f \in R_0$ can be put into a normal form $f^* \equiv f$ modulo $I$, where if $x_n^k$ occurs in $f^*$ then $n \neq f(m), g(m)$ for all $m < k$. Thus $f \in I$ if and only if $f^* = 0$, so $I$ exists by $\Delta_1^0$ comprehension. Form the quotient ring $R = R_0/I$. By our assumption 3, let $J$ be a radical ideal in $R$. Let $J_0$ be the ideal in $R_0$ which corresponds to $J$. Then $J_0$ is a radical ideal in $R_0$ and $I \subseteq J_0$. It follows that $x_{f(m)} \in J_0$ and $x_{g(m)} \notin J_0$ for all $m \in \mathbb{N}$. Setting $X = \{n : x_n \in J_0\}$ we obtain $\forall m \, (f(m) \in X \wedge g(m) \notin X)$. Thus by IV.4.4 we have weak König's lemma. This completes the proof. □

COROLLARY IV.6.5. $\mathsf{RCA}_0$ *is not strong enough to prove that every countable commutative ring has a prime* (*or even radical*) *ideal.*

PROOF. Immediate from theorem IV.6.4 and the fact (to be proved in §VIII.2) that the theorems of $\mathsf{RCA}_0$ are strictly included in those of $\mathsf{WKL}_0$. □

EXERCISE IV.6.6. Show that the following is provable in $\mathsf{WKL}_0$. Let $R$ be a countable commutative ring. Let $\varphi(a)$ and $\psi(a)$ be $\Sigma_1^0$ such that

1. $\forall a \, \forall b \, ((\varphi(a) \wedge \psi(b)) \to (a \in R \wedge b \in R \wedge a \neq b))$,
2. $\varphi(0) \wedge \psi(1)$,
3. $\forall a \, \forall b \, ((\varphi(a) \wedge \varphi(b)) \to \varphi(a + b))$,
4. $\forall a \, \forall r \, ((\varphi(a) \wedge r \in R) \to \varphi(r \cdot a))$,
5. $\forall a \, \forall b \, ((\psi(a) \wedge \psi(b)) \to \psi(a \cdot b))$.

Then $R$ has a prime ideal $P$ such that $\forall a\,(\varphi(a) \to a \in P)$ and $\forall a\,(\psi(a) \to a \notin P)$.

**Notes for §IV.6.** The main results in this section are from Friedman/Simpson/Smith [78, 79].

## IV.7. Fixed Point Theorems

In this and the next two sections, we resume the study of analysis in $\mathsf{WKL}_0$, which was begun in §§IV.1 and IV.2.

A famous theorem of Brouwer states that any continuous mapping of a $k$-simplex into itself has a fixed point. The purpose of this section is to show that Brouwer's theorem and its generalization to infinite-dimensional spaces are provable in $\mathsf{WKL}_0$. We shall also obtain a reversal showing that Brouwer's theorem is equivalent to weak König's lemma over $\mathsf{RCA}_0$.

We begin by presenting one of the well known proofs of Brouwer's theorem, within $\mathsf{WKL}_0$. We use the proof via Sperner's lemma.

Definition IV.7.1 ($k$-simplices). The following definitions are made in $\mathsf{RCA}_0$. For $k \in \mathbb{N}$, a *$k$-simplex* $S$ is the convex hull of $k+1$ affinely independent points $s_0, \ldots, s_k$ in $\mathbb{R}^n$, called the *vertices* of $S$. We can coordinatize $S$ by identifying each point $x \in S$ with the unique $(k+1)$-tuple $(x_0, \ldots, x_k)$ such that $x = \sum_{i=0}^k x_i s_i$, $\sum_{i=0}^k x_i = 1$, and $x_i \geq 0$ for all $i \leq k$. Clearly $S$ is a compact metric space.

If $S$ is a simplex, a *face* of $S$ is any simplex whose vertices are a subset of the vertices of $S$. For any point $x \in S$, the *carrier* of $x$ is the smallest face of $S$ which contains $x$.

Definition IV.7.2 (simplicial subdivision). Within $\mathsf{RCA}_0$, let $S$ be a $k$-simplex. A *simplicial subdivision* of $S$ is a finite set of $k$-simplices $S_0, \ldots, S_m$ such that $S = S_0 \cup \cdots \cup S_m$ and, for all $i < j \leq m$, $S_i \cap S_j$ is either empty or a common face of $S_i$ and $S_j$.

Definition IV.7.3 (admissible labeling). Within $\mathsf{RCA}_0$, let $S$ be a $k$-simplex, and let $P$ be a finite set of points in $S$ which includes the vertices of $S$. An *admissible labeling of $P$* is a mapping from $P$ into $\{0, \ldots, k\}$ such that (i) the vertices of $S$ are mapped to the full set of labels $\{0, \ldots, k\}$; and (ii) for every $x \in P$, the label of $x$ is the same as the label of one of the vertices of the carrier of $x$.

Lemma IV.7.4 (Sperner's lemma). *The following is provable in* $\mathsf{RCA}_0$. *Let $S$ be a $k$-simplex, $k \in \mathbb{N}$, and let $S_0, \ldots, S_m$ be a simplicial subdivision of $S$. Suppose that the vertices of $S_0, \ldots, S_m$ are admissibly labeled. Then for some $i \leq m$, the vertices of $S_i$ are mapped to the full set of labels $\{0, \ldots, k\}$.*

PROOF. The proof consists of elementary combinatorial reasoning which is straightforwardly formalized in $\mathsf{RCA}_0$. We shall now present this proof.

We shall actually prove that the number of $S_i$'s receiving a full set of labels is odd. The proof is by induction on $k$. For $k = 0$ the result is trivial. For $k = 1$, note that $S$ is a line segment and $S_0, \ldots, S_m$ is a partition of $S$ into subsegments. Since the endpoints of $S$ are labeled 0 and 1, it is clear that there are an odd number of $S_i$'s whose endpoints are labeled 0 and 1. This is the base of the induction.

Now suppose $k > 1$. Let $T$ be the face of $S$ with vertices labeled $\{0, \ldots, k-1\}$. Let $T_0, \ldots, T_n$ be the simplicial subdivision of $T$ induced by $S_0, \ldots, S_m$. Clearly the induced labeling of the vertices of $T_0, \ldots, T_n$ is admissible. Hence by induction hypothesis the number of $T_j$'s with vertices labeled $\{0, \ldots, k-1\}$ is odd. For $i \leq m$ let $d_i$ be the number of faces of $S_i$ with vertices labeled $\{0, \ldots, k-1\}$. By admissibility, each such face is either one of the $T_j$'s or a common face of two $S_i$'s. Since the number of such faces which are $T_j$'s is odd, it follows that $d_0 + \cdots + d_m$ is odd. Hence there are an odd number of $S_i$'s with $d_i$ odd. But if $d_i$ is odd, it is easy to see that $d_i = 1$, and this holds if and only if the vertices of $S_i$ receive the full set of labels $\{0, \ldots, k\}$. This completes the proof. □

LEMMA IV.7.5. *The following is provable in* $\mathsf{WKL}_0$. *Let $S$ be a $k$-simplex. Then every continuous function $f : S \to S$ has a fixed point, i.e., $f(x) = x$ for some $x \in S$.*

PROOF. We reason in $\mathsf{WKL}_0$. Suppose the conclusion fails. Then $|f(x) - x| > 0$ for all $x \in S$. By a simple argument involving the Heine/Borel property (cf. exercise IV.2.10), we see that there exists $\epsilon > 0$ such that $|f(x) - x| > \epsilon$ for all $x \in S$. Put $\epsilon^* = \epsilon/(3k+3)$. Let $\varphi(x, i)$ be a $\Sigma^0_1$ formula which says that $i \leq k$, $x_i > 0$ and $y_i < x_i + \epsilon^*$, where $x = (x_0, \ldots, x_k)$ and $f(x) = y = (y_0, \ldots, y_k)$. It is clear that, for each $x \in S$, $\varphi(x, i)$ holds for at least one $i \leq k$.

By theorem IV.2.2, $f$ is uniformly continuous, so let $\delta > 0$ be such that $|x - x'| < \delta$ implies $|f(x) - f(x')| < \epsilon^*$. Let $S_0, \ldots, S_n$ be a subdivision of $S$ into $k$-simplices of diameter less than the minimum of $\delta$ and $\epsilon^*$. If $x$ is any vertex of this simplicial subdivision, we define $\text{label}(x) = i$ for some $i$ such that $\varphi(x, i)$ holds. It is straightforward to verify that this labeling is admissible, so by Sperner's lemma in $\mathsf{RCA}_0$ (lemma IV.7.4) there exists $j$ such that the vertices of $S_j$ receive a full set of labels. It is then easy to see that $|f(x') - x'| < \epsilon$ holds for any $x' \in S_j$. This contradiction completes the proof. □

The following is our version of Brouwer's fixed point theorem.

THEOREM IV.7.6 (Brouwer fixed point theorem in $\mathsf{WKL}_0$). *The following is provable in* $\mathsf{WKL}_0$. *Let $C$ be the convex hull of a nonempty finite set of points in $\mathbb{R}^n$, $n \in \mathbb{N}$. Then every continuous function $f : C \to C$ has a fixed point.*

Proof. Let $k$ be the dimension of $C$. We can find a $k$-simplex $S$ in $\mathbb{R}^n$ such that $C \subseteq S$. Using elementary linear algebra in $\mathsf{RCA}_0$ (cf. exercise II.4.11), we can show that $C$ is a *retract* of $S$, i.e., there is a continuous function $r\colon S \to C$ such that $r(x) = x$ for all $x \in C$. Given a continuous function $f\colon C \to C$, consider $g\colon S \to C$ given by $g(x) = f(r(x))$. By theorem IV.7.5, let $x \in S$ be such that $g(x) = x$. Then $x \in C$, hence $r(x) = x$, hence $f(x) = g(x) = x$. This completes the proof. □

We shall now obtain a reversal showing that weak König's lemma is needed to prove Brouwer's theorem, even for the unit square.

Theorem IV.7.7 (reversal). *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Let $C$ be the convex hull of a nonempty finite set of points in $\mathbb{R}^n$, $n \in \mathbb{N}$. Then every continuous function $f : C \to C$ has a fixed point.*
2. *Let $C$ be the unit square, $[0,1]\times[0,1]$. Then every continuous function $f : C \to C$ has a fixed point.*
3. *Weak König's lemma.*

Proof. The implication $1 \to 2$ is trivial, and $3 \to 1$ has already been proved as theorem IV.7.6. It remains to prove $2 \to 3$. Working within $\mathsf{RCA}_0$, assume that weak König's lemma is false. Let $T \subseteq 2^{<\mathbb{N}}$ be an infinite tree with no infinite path. We shall use $T$ to construct a continuous function $f : C \to C$ with no fixed point, where $C = [0,1] \times [0,1]$.

Let $\partial C$ be the boundary of $C$, i.e., the four edges of the unit square. It suffices to show that $\partial C$ is a retract of $C$. For, once we have a retraction map $r\colon C \to \partial C$, we can let $f : C \to \partial C$ consist of $r$ followed by a $90^o$ rotation of $\partial C$. Clearly such an $f$ has no fixed point.

We claim that there exists a *singular covering* of $[0,1]$, i.e., a covering of $[0,1]$ by an infinite sequence of closed rational intervals $I_n = [a_n, b_n]$, $a_n, b_n \in \mathbb{Q}$, $a_n < b_n$, $n \in \mathbb{N}$, such that for all $m \neq n$, $I_m \cap I_n$ consists of at most one point. To see this, define intervals $[c_\sigma, d_\sigma]$, $\sigma \in 2^{<\mathbb{N}}$, by putting $c_{\langle\rangle} = 0$, $d_{\langle\rangle} = 1$, $c_{\sigma^\frown\langle 0\rangle} = c_\sigma$, $c_{\sigma^\frown\langle 1\rangle} = d_{\sigma^\frown\langle 0\rangle} = (c_\sigma + d_\sigma)/2$, and $d_{\sigma^\frown\langle 1\rangle} = d_\sigma$. Let $\langle \sigma_n : n \in \mathbb{N}\rangle$ be an enumeration of $\widetilde{T} = \{\sigma \in 2^{<\mathbb{N}} : \sigma \notin T \wedge \sigma[\mathrm{lh}(\sigma) - 1] \in T\}$, and put $I_n = [a_n, b_n] = [c_{\sigma_n}, d_{\sigma_n}]$. Clearly $\langle I_n : n \in \mathbb{N}\rangle$ has the desired properties, so our claim is proved.

For each $n \in \mathbb{N}$, put

$$A_n = \left(\bigcup_{m\le n} I_m \times I_n\right) \cup \left(\bigcup_{m\le n} I_n \times I_m\right)$$

and

$$B_n = ([0,1] \times I_n) \cup (I_n \times [0,1]).$$

Note that $C = \bigcup_{n\in\mathbb{N}} A_n$. Note also that $A_n$ is properly included in $B_n$.

Our retraction map $r\colon C \to \partial C$ will be defined in stages. We begin by defining $r$ on $\partial C$ to be the identity map. At stage $n$, we assume that $r$ has already been defined on $\partial C$ and on $A_m$ for all $m < n$, and we define $r$ on $A_n$. Let $P_{n0}, \ldots, P_{nk_n}$ be the connected components of $A_n$. Since $A_n$ is properly included in $B_n$, it follows that $\partial P_{ni}$ has at least one edge $e_{ni}$ which, except for its endpoints, lies inside $B_n \setminus \partial C$, hence is disjoint from $\bigcup_{m<n} A_m$. Let $e'_{ni}$ be $e_{ni}$ minus its endpoints. We define $r$ on $P_{ni}$ to consist of a continuous retraction of $P_{ni}$ onto $\partial P_{ni} \setminus e'_{ni}$, followed by a continuous mapping of $\partial P_{ni} \setminus e'_i$ into $\partial C$ which is compatible with the part of $r$ that has already been defined. This defines $r$ on $A_n = \bigcup_{i \le k_n} P_{ni}$.

It can be shown that the above construction gives rise to a continuous function $r$ defined on all of $C = \bigcup_{n\in\mathbb{N}} A_n$. Clearly $r$ is a retraction of $C$ onto $\partial C$. This completes the proof. □

We shall now obtain an infinite-dimensional generalization of Brouwer's theorem, within $\mathsf{WKL}_0$. The theorem which we shall prove is closely related to the Schauder/Tychonoff fixed point theorem. First, we need the following technical lemma.

LEMMA IV.7.8. *The following is provable in* $\mathsf{WKL}_0$. *Let $C$ be a closed set in a compact metric space $X$. Given $\epsilon > 0$, there exists a finite set of points $c_1, \ldots, c_m \in C$ such that for all $x \in C$, $d(x, c_i) < \epsilon$ for some $i$, $1 \le i \le m$.*

PROOF. By compactness, there exists a finite set of points $x_1, \ldots, x_n \in X$ such that for all $x \in X$ there exists $i$ such that $d(x, x_i) < \epsilon/2$. By theorem IV.1.7, we see that the formula

$$\varphi(i) \equiv \exists x\, (x \in C \text{ and } d(x, x_i) \le \epsilon/2)$$

is equivalent to a $\Pi^0_1$ formula. By bounded $\Pi^0_1$ comprehension, let $I \subseteq \{1, \ldots, n\}$ be the set of $i$ such that $\varphi(i)$ holds. By theorem IV.1.8, let $\langle c_i : i \in I\rangle$ be a sequence of points such that $c_i \in C$ and $d(c_i, x_i) \le \epsilon/2$. Then for all $x \in C$ we have $d(x, x_i) < \epsilon/2$ for some $i$, hence $i \in I$, hence $d(c_i, x_i) \le \epsilon/2$, hence $d(x, c_i) < \epsilon$. We can renumber the $c_i$'s as $c_1, \ldots, c_m$ where $m = |I| \le n$. This completes the proof. □

The following is our version of the Schauder/Tychonoff fixed point theorem. Recall from examples II.5.5 and III.2.6 that the Hilbert cube $[0, 1]^{\mathbb{N}}$ is compact.

THEOREM IV.7.9 (Schauder fixed point theorem in $\mathsf{WKL}_0$). *The following is provable in* $\mathsf{WKL}_0$. *Let $C$ be a nonempty closed convex set in $[-1, 1]^{\mathbb{N}}$. Then every continuous function $f : C \to C$ has a fixed point.*

PROOF. Suppose not. Let $f : C \to C$ be continuous such that $f(x) \neq x$ for all $x \in C$. For $m \ge 1$ and $x = \langle x_i : i \in \mathbb{N}\rangle \in \mathbb{R}^{\mathbb{N}}$, we put $\|x\|_m = \max_{i<m} |x_i|$. Let us write $\mathrm{B}_m(x, \epsilon)$ (respectively $\mathrm{B}^*_m(x, \epsilon)$) for the open (respectively closed) ball consisting of all $y \in \mathbb{R}^{\mathbb{N}}$ such that $\|y - x\|_m < \epsilon$ (respectively $\|y - x\|_m \le \epsilon$). By the Heine/Borel covering

principle in $\mathsf{WKL}_0$ (theorem IV.1.5), there exist $m \in \mathbb{N}$ and $\epsilon > 0$ such that $f(x) \notin \mathrm{B}_m(x, \epsilon)$ for all $x \in C$. We shall obtain a contradiction by finding a point $x \in C$ such that $f(x) \in \mathrm{B}_m(x, \epsilon)$.

By the previous lemma, let $c_0, \ldots, c_k \in C$ be such that $C$ is covered by the open sets $U_i = \mathrm{B}_m(c_i, \epsilon)$, $i \leq k$. Let $D \subseteq C$ be the convex hull of $c_0, \ldots, c_k$. Recall from example II.5.5 that $\mathbb{R}^{\mathbb{N}} = \widehat{A}$ where $A$ is the set of eventually 0 sequences of rational numbers. Let $\varphi(k, a, r, i)$ be a $\Sigma^0_1$ formula which says that $n \in \mathbb{N}$, $a \in A$, $r \in \mathbb{Q}^+$, $i \leq k$, and

$$\mathrm{B}^*_n(a, r) \subseteq (\mathbb{R}^{\mathbb{N}} \setminus C) \cup f^{-1}(U_i).$$

It is straightforward to show that $\mathbb{R}^{\mathbb{N}}$ is covered by open sets $\mathrm{B}_n(a, r)$ such that $\varphi(k, a, r, i)$ holds for some $i \leq k$. Hence by the Heine/Borel principle there exists a covering of $C$ by finitely many open sets $\mathrm{B}_{n_{ij}}(a_{ij}, r_{ij})$, $i \leq k$, $j < l_i$, with $\varphi(k_{ij}, a_{ij}, r_{ij}, i)$. Put $V_i = \bigcup_{j<l_i} \mathrm{B}_{n_{ij}}(a_{ij}, r_{ij})$. Thus $C$ is covered by the open sets $V_i$, $i \leq k$, and $f(V_i) \subseteq U_i$. Put

$$n = \max\{m\} \cup \{n_{ij} : i \leq k, j < l_i\}.$$

For any $x = \langle x_i : i \in \mathbb{N}\rangle \in \mathbb{R}^{\mathbb{N}}$, let us write $\overline{x} = \langle x_i : i < n\rangle \in \mathbb{R}^n$. Let $\overline{D}$ be the convex hull of $\overline{c}_0, \ldots, \overline{c}_k$ in $\mathbb{R}^k$, and let $\overline{V}_i = \bigcup_{j<l_i} \mathrm{B}_{n_{ij}}(\overline{a}_{ij}, r_{ij}) \subseteq \mathbb{R}^n$. Thus $\overline{D}$ is covered by open sets $\overline{V}_i$, $i \leq k$, in $\mathbb{R}^n$. As in the proof of theorem II.7.2, let $g_i : \overline{D} \to [0, 1]$, $i \leq k$, be a sequence of continuous functions such that $\sum_{i=0}^k g_i(x) = 1$ for all $\overline{x} \in \overline{D}$, and $g_i(\overline{x}) > 0$ implies $\overline{x} \in \overline{V}_i$. Define $g : \overline{D} \to \overline{D}$ by $g(\overline{x}) = \sum_{i=0}^k g_i(\overline{x})\overline{c}_i$.

By theorem IV.7.6, there is $\overline{x}' \in \overline{D}$ such that $g(\overline{x}') = \overline{x}'$. Put

$$x' = \sum_{i=0}^{k} g_i(\overline{x}')c_i$$

and note that $x' \in C$. By bounded $\Sigma^0_1$ comprehension, let $I$ be the set of all $i \leq k$ such that $g_i(\overline{x}') > 0$. Then for all $i \in I$ we have $\overline{x}' \in \overline{V}_i$, hence $x' \in V_i$, hence $f(x') \in U_i = \mathrm{B}_m(c_i, \epsilon)$, i.e., $\|f(x') - c_i\|_m < \epsilon$. Since $\sum g_i(\overline{x}') = 1$, it follows that

$$\begin{aligned} \|f(x') - x'\|_m &= \left\| \sum_{i\in I} g_i(\overline{x}')f(x') - \sum_{i\in I} g_i(\overline{x}')c_i \right\|_m \\ &\leq \sum_{i\in I} g_i(\overline{x}')\|f(x') - c_i\|_m < \epsilon. \end{aligned}$$

Thus $f(x') \in \mathrm{B}_m(x', \epsilon)$ and the proof is complete. □

**Notes for §IV.7.** Shioji/Tanaka [219] proved versions of the Brouwer and Schauder fixed point theorems, within $\mathsf{WKL}_0$. Our results in this section

are variants of those of Shioji/Tanaka [219]. Our proof of Brouwer's theorem within $\mathsf{WKL}_0$ is modeled after the well known proof of Brouwer's theorem via Sperner's lemma (cf. Tompkins [267]). The fact that Brouwer's theorem for $[0,1]\times[0,1]$ implies weak König's lemma is due to Shioji/Tanaka [219], based on a recursive counterexample due to Orevkov [199].

## IV.8. Ordinary Differential Equations

In this section we discuss Peano's existence theorem for solutions of ordinary differential equations. Peano's theorem says that, if $f(x,y)$ is continuous in some neighborhood of $(0,0)$, then the initial value problem

$$y' = f(x,y), \qquad y(0) = 0 \tag{12}$$

has a solution $y = \phi(x)$ which is continuously differentiable in some neighborhood of $x = 0$. Here $y'$ denotes the derivative of the unknown function $y = y(x)$. We shall show that Peano's theorem is provable in $\mathsf{WKL}_0$. We shall also show that Peano's theorem is equivalent to weak König's lemma over $\mathsf{RCA}_0$.

We begin by proving Peano's theorem in $\mathsf{WKL}_0$. The proof will be based on theorem IV.7.9, our $\mathsf{WKL}_0$ version of the Schauder fixed point theorem.

THEOREM IV.8.1 (Peano's theorem in $\mathsf{WKL}_0$). *The following is provable in* $\mathsf{WKL}_0$. *Let $f(x,y)$ be a continuous real-valued function on the rectangle $-a \le x \le a$, $-b \le y \le b$ where $a, b > 0$. Then the initial value problem*

$$\frac{dy}{dx} = f(x,y), \qquad y(0) = 0$$

*has a continuously differentiable solution $y = \phi(x)$ on the interval $-\alpha \le x \le \alpha$, $\alpha = \min(a, b/M)$, where*

$$M = \max\{|f(x,y)| : -a \le x \le a, -b \le y \le b\}.$$

PROOF. We reason in $\mathsf{WKL}_0$.

Note first that $M$ exists by theorem IV.2.2.

Let $A = \{q_i : i \in \mathbb{N}\}$ be an enumeration of the rational numbers in the closed interval $[-\alpha, \alpha]$. Thus $\widehat{A} = [-\alpha, \alpha]$. We may safely assume that $q_0 = 0$. Let $C$ be the closed convex set in $\mathbb{R}^{\mathbb{N}}$ consisting of all sequences $\langle y_i : i \in \mathbb{N}\rangle$ such that $y_0 = 0$ and $|y_i - y_j| \le M \cdot |q_i - q_j|$ for all $i, j \in \mathbb{N}$. $C$ is included in the compact product space $\prod_{i\in\mathbb{N}}[-M\alpha, M\alpha]$ (cf. lemma III.2.5).

To each $\langle y_i : i \in \mathbb{N}\rangle \in C$ is associated a continuous function

$$\phi : [-\alpha, \alpha] \to \mathbb{R}$$

such that $\phi(q_i) = y_i$ for all $i \in \mathbb{N}$. Namely, the code $\Phi$ of $\phi$ is given by putting $(q_i, r)\Phi(b, s)$ if and only if $M \cdot r + |b - y_i| < s$. Thus we shall identify points of $C$ with continuous functions $\phi\colon [-\alpha, \alpha] \to \mathbb{R}$ satisfying $\phi(0) = 0$ and

$$|\phi(x) - \phi(x')| \leq M \cdot |x - x'|$$

for $|x|, |x'| \leq \alpha$.

We define a continuous function $F\colon C \to C$ as follows. For $\langle y_i : i \in \mathbb{N}\rangle \in C$, we put

$$F(\langle y_i : i \in \mathbb{N}\rangle) = \left\langle \int_0^{q_i} f(x, \phi(x))\, dx : i \in \mathbb{N} \right\rangle$$

where $\phi\colon [-\alpha, \alpha] \to \mathbb{R}$ is the continuous function associated to $\langle y_i : i \in \mathbb{N}\rangle$ as in the previous paragraph. For all $i, j \in \mathbb{N}$ we have

$$\begin{aligned}\left| \int_0^{q_i} f(x, \phi(x))\, dx - \int_0^{q_j} f(x, \phi(x))\, dx \right| &= \left| \int_{q_i}^{q_j} f(x, \phi(x))\, dx \right| \\ &\leq M \cdot |q_i - q_j|\end{aligned}$$

so $F(\langle y_i : i \in \mathbb{N}\rangle) \in C$. Using a modulus of uniform continuity for $f$ (cf. theorem IV.2.2), it is straightforward to construct a code for $F$.

Now by theorem IV.7.9 let $\langle y_i : i \in \mathbb{N}\rangle \in C$ be a fixed point of $F$, i.e.,

$$F(\langle y_i : i \in \mathbb{N}\rangle) = \langle y_i : i \in \mathbb{N}\rangle.$$

Let $\phi\colon [-\alpha, \alpha] \to \mathbb{R}$ be the continuous function associated to $\langle y_i : i \in \mathbb{N}\rangle$. Then for all $i \in \mathbb{N}$ we have

$$\phi(q_i) = \int_0^{q_i} f(x, \phi(x)) dx.$$

It follows easily that

$$\frac{d\phi(x)}{dx} = f(x, \phi(x)) \text{ and } \phi(0) = 0$$

for all $x$ in $[-\alpha, \alpha]$. This proves our theorem. □

We remark that it is straightforward to extend the previous theorem so as to apply to initial value problems of the form

$$\begin{aligned} y_1' &= f_1(x, y_1, \ldots, y_n), & y_1(0) &= 0 \\ y_2' &= f_2(x, y_1, \ldots, y_n), & y_2(0) &= 0 \\ &\vdots \\ y_n' &= f_n(x, y_1, \ldots, y_n), & y_n(0) &= 0 \end{aligned}$$

where $n \in \mathbb{N}$.

We now turn to the reversal of theorem IV.8.1. The following theorem says that Peano's theorem is equivalent over $\mathsf{RCA}_0$ to weak König's lemma.

THEOREM IV.8.2 (reversal). *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{WKL}_0$.
2. *Peano's theorem, as stated in* IV.8.1.
3. *If* $f(x, y)$ *is continuous and has a modulus of uniform continuity in some neighborhood of* $x = 0$, $y = 0$, *then the initial value problem* (12) *has a continuously differentiable solution* $y = \phi(x)$ *in some interval containing* $x = 0$.

PROOF. The implication from 1 to 2 is given by theorem IV.8.1, and the implication from 2 to 3 is trivial. It remains to prove that 3 implies 1. Assume 3. Instead of proving weak König's lemma directly, we shall prove $\Sigma^0_1$ separation (lemma IV.4.4.2).

Let $\varphi(n, i)$ be a $\Sigma^0_1$ formula such that $\neg\exists n\,(\varphi(n, 0) \wedge \varphi(n, 1))$. Working in $\mathsf{RCA}_0$, we shall construct a a continuous function $f(x, y)$ on the rectangle $|x| \leq 1$, $|y| \leq 1$, such that $|f(x, y)| \leq 1$, $f(-x, y) = -f(x, y)$, and for each $n \geq 1$, if $y = \phi(x)$ is any solution of $y' = f(x, y)$ on the interval $-2^{-n+1} \leq x \leq -2^{-n}$, then

$$\phi(-2^{-n+1}) = \phi(-2^{-n}); \tag{13}$$

$$\varphi(n, 0) \text{ and } \phi(-2^{-n+1}) = 0 \text{ imply } \phi(-2^{-n} - 2^{-n-1}) > 2^{-3(n+2)}; \tag{14}$$

$$\varphi(n, 1) \text{ and } \phi(-2^{-n+1}) = 0 \text{ imply } \phi(-2^{-n} - 2^{-n-1}) < 2^{-3(n+2)}. \tag{15}$$

Moreover, $f(x, y)$ will have a modulus of uniform continuity on the rectangle $|x| \leq 1, |y| \leq 1$.

Once we obtain $f(x, y)$ as above, we can apply IV.8.2.3 to get a continuously differentiable function $\phi(x)$ which is a solution of the initial value problem (12) on some interval containing $x = 0$. Using the property $f(-x, y) = -f(x, y)$, we may assume that $\phi(x)$ is a solution of (12) on some interval of the form

$$-2^{-N} \leq x \leq 0,$$

where $N \in \mathbb{N}$. By (13) we have $\phi(-2^{-n+1}) = \phi(-2^{-n})$ for all $n > N$. Since $\phi(0) = 0$ and $\phi$ is continuous, it follows by $\Sigma^0_1$ induction that $\phi(-2^{-n+1}) = 0$ for all $n > N$. Hence by (14) we have that $\varphi(n, 0)$ implies $\phi(-2^{-n} - 2^{-n-1}) > -2^{-3(n+2)}$, while by (15) we have that $\varphi(n, 1)$ implies $\phi(-2^{-n} - 2^{-n-1}) < -2^{-3(n+2)}$, for all $n > N$. Let $A$ be the set of rational numbers in the interval $|x| \leq 2^{-N}$, and let $\Phi$ be a code for $\phi$. By minimization (theorem II.3.5), there exists

$$g : \mathbb{N} \setminus \{0, 1, \ldots, N\} \to \mathbb{N} \times A \times \mathbb{Q}^+ \times A \times \mathbb{Q}^+$$

defined by $g(n) =$ the least $(k, a, r, b, s) \in \Phi$ such that

$$\left|a - (-2^{-n} - 2^{-n-1})\right| < r \text{ and } s < 2^{-3(n+2)}.$$

Writing $g(n) = (k_n, a_n, r_n, b_n, s_n)$, we have

$$\left|b_n - \phi(-2^{-n} - 2^{-n-1})\right| < 2^{-3(n+2)}.$$

By $\Delta_1^0$ comprehension, let $X$ be the set of $n > N$ such that $b_n > 0$. Thus for $n > N$ we have $\varphi(n, 0)$ implies $n \in X$, while $\varphi(n, 1)$ implies $n \notin X$. This together with bounded $\Sigma_1^0$ comprehension (theorem II.3.9) gives $\Sigma_1^0$ separation. Hence by lemma IV.4.4 we have weak König's lemma.

It remains to construct $f(x, y)$ as above. We shall need certain auxiliary functions $h_n(x)$ and $j_n(x, y)$, $n \in \mathbb{N}$.

Write $\varphi(n, i)$ as $\exists m\, \theta(m, n, i)$ where $\theta$ is $\Sigma_0^0$. Define

$$q(x) = \max(1 - |x|, 0).$$

For $n \in \mathbb{N}$ define

$$h_n(x) = \begin{cases} 2^{-k} \cdot q\left(2^k \left(x - \frac{1}{2}\right)\right) & \text{if } k = \text{least } m \text{ such that } \theta(m, n, 0), \\ -2^{-k} \cdot q\left(2^k \left(x - \frac{1}{2}\right)\right) & \text{if } k = \text{least } m \text{such that } \theta(m, n, 1), \\ 0 & \text{otherwise.} \end{cases}$$

Thus $\varphi(n, 0)$ (respectively $\varphi(n, 1)$) implies that $h_n(x)$ is positive (respectively negative) on an interval of length $2^{-k+1}$ centered at $x = 1/2$, where $k =$ the least $m$ such that $\theta(m, n, 0)$ (respectively $\theta(m, n, 1)$) holds.

We shall need information on the solutions of the equation

$$y' = s(x, y) = 9x(1 - x)y^{1/3}.$$

It is easy to verify that $y' = s(x, y)$ with initial condition $y(0) = y_0$ has on the interval $0 \le x \le 1$ the unique solution

$$y(x) = (\operatorname{sgn} y_0)\,[x^2(3 - 2x) + |y_0|^{2/3}]^{3/2}$$

for $y_0 \neq 0$. Here $\operatorname{sgn} t = 1$ if $t > 0, -1$ if $t < 0$. For $y_0 = 0$, there is a family of solutions

$$y(x) = \begin{cases} 0 & \text{for } 0 \le x \le c, \\ \pm[x^2(3 - 2x) - c^2(3 - 2c)]^{3/2} & \text{for } c \le x \le 1, \end{cases}$$

where $0 \le c \le 1$. Each possible real value for $y(1)$ is assumed by exactly one of these solutions. Also, if a solution $y(x)$ has $y(x_0) \neq 0$ where $0 \le x_0 < 1$, then $|y(x)|$ must increase throughout the interval $x_0 \le x \le 1$. Thus the indicated solutions are the only ones on the interval $0 \le x \le 1$.

Now we define the functions $j_n(x, y)$, $n \in \mathbb{N}$, by

$$j_n(x, y) = \begin{cases} h_n(x) & \text{for } 0 \le x \le 1, \\ s(x - 1, y) & \text{for } 1 \le x \le 2, \\ -s(x - 2, y) & \text{for } 2 \le x \le 4, \\ -h_n(x - 3) & \text{for } 3 \le x \le 4. \end{cases}$$

If $y(x)$ is a solution of $y' = j_n(x, y)$ over $0 \leq x \leq 4$, then $y(2)$ determines $y(x)$ throughout $1 \leq x \leq 2$ and hence also $0 \leq x \leq 1$. Using the identities $h_n(x) = h_n(1 - x)$ and $s(x, y) = s(1 - x, y)$, we have $j_n(x, y) = -j_n(4 - x, y)$. This implies that $y_1(x) = y(4 - x)$ is also a solution over $0 \leq x \leq 4$. Since $y_1(2) = y(2)$, we have $y_1(x) = y(x)$ in the interval $0 \leq x \leq 2$. It now follows that $y(x) = y(4 - x)$ for $0 \leq x \leq 4$. Thus, if $y(x)$ is any solution of $y' = j_n(x, y)$ on $0 \leq x \leq 4$, we have $y(0) = y(4)$. If in addition $y(0) = 0$, then we have $y(2) > 1$ if $\varphi(n, 0)$, $y(2) < -1$ if $\varphi(n, 1)$, and $-1 \leq y(2) \leq 1$ if $\neg\varphi(n, 0) \wedge \neg\varphi(n, 1)$.

Finally, define $f(x, y)$ for $x \leq 0$ by

$$f(x, y) = \sum_{n=1}^{\infty} 2^{-2(n+2)} j_n(2^{n+2}(x + 2^{-n+1}), 2^{3(n+2)} y),$$

and for $x \geq 0$ by $f(x, y) = -f(-x, y)$. Note that under the transformation

$$\widehat{x} = 2^{n+2}(x + 2^{-n+1}),$$
$$\widehat{y} = 2^{3(n+2)} \cdot y,$$

a solution of $y' = j_n(x, y)$ on the interval $0 \leq x \leq 4$ becomes a solution of

$$y' = 2^{-2(n+2)} \cdot j_n(2^{n+2}(x + 2^{-n+1}), 2^{3(n+2)} y)$$

on the interval $-2^{-n+1} \leq x \leq -2^{-n}$. The properties of $f(x, y)$ listed earlier are now easily verified.

This completes the proof. □

A consequence of the previous theorem is that Peano's existence theorem for solutions of ordinary differential equations is not provable in $\mathsf{RCA}_0$. In view of this fact, it is interesting to note that a version of Picard's existence and uniqueness theorem is provable in $\mathsf{RCA}_0$. We formalize this as follows.

THEOREM IV.8.3 (Picard's theorem in $\mathsf{RCA}_0$). *The following is provable in* $\mathsf{RCA}_0$. *Assume that* $f(x, y)$ *has a modulus of uniform continuity* $h : \mathbb{N} \to \mathbb{N}$ *and satisfies a Lipschitz condition*

$$|f(x, y_1) - f(x, y_2)| \leq L \cdot |y_1 - y_2|$$

*and* $|f(x, y)| \leq M$ *throughout the rectangle* $-a \leq x \leq a$, $-b \leq y \leq b$, *where* $L$, $M$, $a$, *and* $b$ *are positive real numbers. Then the initial value problem* (12) *has a unique solution* $y = \phi(x)$ *on the interval* $-\alpha \leq x \leq \alpha$, $\alpha = \min(a, b/M)$. *Moreover* $\phi(x)$ *has a modulus of uniform continuity on this interval.*

PROOF. We reason in $\mathsf{RCA}_0$.

As in the proof of theorem IV.8.1, let $C$ be the compact convex set consisting of all continuous real-valued functions $\phi(x)$, $|x| \leq \alpha$, satisfying

$\phi(0) = 0$ and with modulus of uniform continuity given by

$$|\phi(x_1) - \phi(x_2)| \leq M \cdot |x_1 - x_2|$$

for $|x_1|, |x_2| \leq \alpha$. Also as in that proof, let $F\colon C \to C$ be given by

$$F(\phi)(x) = \int_0^x f(\xi, \phi(\xi))\, d\xi.$$

Define a sequence of functions $\phi_n \in C$, $n \in \mathbb{N}$, by putting $\phi_0(x) = 0$ for all $|x| \leq \alpha$, and $\phi_{n+1} = F(\phi_n)$ for all $n \in \mathbb{N}$. We claim that, for all $n \in \mathbb{N}$,

$$|\phi_{n+1}(x) - \phi_n(x)| \leq \frac{L^n M |x|^{n+1}}{(n+1)!}. \tag{16}$$

In proving this claim, the base step $n = 0$ is given by

$$|\phi_1(x) - \phi_0(x)| = \left| \int_0^x f(\xi, 0)\, d\xi \right| \leq M|x|.$$

For the inductive step, note that (16) implies

$$\begin{aligned} |\phi_{n+2}(x) - \phi_{n+1}(x)| &\leq \int_0^x |f(\xi, \phi_{n+1}(\xi)) - f(\xi, \phi_n(\xi))|\, d\xi \\ &\leq L \cdot \int_0^x |\phi_{n+1}(\xi) - \phi_n(\xi)|\, d\xi \\ &\leq \frac{L^{n+1} M}{(n+1)!} \int_0^x |\xi|^{n+1}\, d\xi \\ &= \frac{L^{n+1} M |x|^{n+2}}{(n+2)!}. \end{aligned}$$

The inequalities (16) together with lemma II.6.5 imply that $\phi_n(x)$ converges uniformly to a function $\phi(x)$ in $C$. It is straightforward to verify that $\phi(x)$ is a fixed point of $F$, i.e.,

$$\phi(x) = \int_0^x f(\xi, \phi(\xi))\, d\xi.$$

Thus $y = \phi(x)$ is a solution to the initial value problem (12).

To prove uniqueness, suppose that $y = \widehat{\phi}(x)$ is another solution, and consider the function

$$\psi(x) = (\phi(x) - \widehat{\phi}(x))^2 e^{-2Lx}.$$

Then we have $\psi(0) = 0$ and, for $x > 0$,

$$\psi'(x) + 2L\psi(x) = 2(\phi(x) - \widehat{\phi}(x))(\phi'(x) - \widehat{\phi}'(x))e^{-2Lx}.$$

The absolute value of the right hand side is

$$\begin{aligned} 2 \cdot |\phi(x) - \widehat{\phi}(x)| \cdot |f(x, \phi(x)) - f(x, \widehat{\phi}(x))| \cdot e^{-2Lx} \\ &\leq 2 \cdot |\phi(x) - \widehat{\phi}(x)| \cdot L \cdot |\phi(x) - \widehat{\phi}(x)| \cdot e^{-2Lx} \\ &= 2L\psi(x) \end{aligned}$$

so $\psi'(x) \leq 0$, hence $\psi(x) \leq \psi(0) = 0$ for $x > 0$. This implies $\psi(x) = 0$ since obviously $\psi(x) \geq 0$ by definition. Thus $\phi(x) = \widehat{\phi}(x)$ for $x \geq 0$. Similarly, by considering

$$\psi(x) = (\phi(x) - \widehat{\phi}(x))^2 e^{2Lx}$$

we obtain $\phi(x) = \widehat{\phi}(x)$ for $x \leq 0$. This completes the proof. □

Once again, we remark that the result of theorem IV.8.3 extends straightforwardly to the case of an initial value problem involving $n$ unknown functions, $n \in \mathbb{N}$.

**Notes for §IV.8.** For a somewhat different treatment of the material in this section, see Simpson [236]. The results of this section are due to Simpson [236]. The proof of Peano's theorem in $\mathsf{WKL}_0$ given here (IV.8.1), based on a $\mathsf{WKL}_0$ version of Schauder's fixed point theorem, is essentially due to Shioji/Tanaka [219]. The fact that Peano's theorem implies weak König's lemma (theorem IV.8.2) is due to Simpson [236], based on a recursive counterexample due to Aberth [2]. See also Pour-El/Richards [203]. Our successive approximation proof of the Picard existence and uniqueness theorem (theorem IV.8.3) follows Aberth [2]. See also Birkhoff/Rota [19, pages 99–115].

## IV.9. The Separable Hahn/Banach Theorem

In §II.10 we developed some of the rudimentary theory of separable Banach spaces, within $\mathsf{RCA}_0$. We shall now show that a version of the Hahn/Banach theorem for separable Banach spaces can be proved in $\mathsf{WKL}_0$. Indeed, this theorem is equivalent to weak König's lemma over $\mathsf{RCA}_0$.

For our $\mathsf{WKL}_0$ proof of the separable Hahn-Banach theorem, we shall use an idea of Kakutani. The following lemma is a $\mathsf{WKL}_0$ version of a famous theorem of functional analysis, known as the Markov/Kakutani fixed point theorem.

Given a closed convex set $C \subseteq \mathbb{R}^{\mathbb{N}}$, a continuous function $f : C \to C$ is called *affine* if

$$f\left(\sum_{i=0}^{k} \alpha_i x_i\right) = \sum_{i=0}^{k} \alpha_i f(x_i)$$

for all $k \in \mathbb{N}$, $x_0, \dots, x_k \in C$, and $\alpha_0, \dots, \alpha_k \geq 0$ with $\sum_{i=0}^{k} \alpha_i = 1$. A sequence of continuous functions $f_n \colon C \to C$, $n \in \mathbb{N}$ is said to be *commutative* if $f_m f_n(x) = f_n f_m(x)$ for all $m, n \in \mathbb{N}$ and $x \in C$.

Lemma IV.9.1 (Markov/Kakutani theorem in $\mathsf{WKL}_0$). *The following is provable in* $\mathsf{WKL}_0$. *Let $C$ be a closed convex set in $[-1,1]^{\mathbb{N}}$. Let $f_n \colon C \to C$, $n \in \mathbb{N}$, be a commutative sequence of continuous affine maps. Then these maps have a common fixed point, i.e., there exists $x \in C$ such that $f_n(x) = x$ for all $n \in \mathbb{N}$.*

Proof. We reason in $\mathsf{WKL}_0$.

For each $n \in \mathbb{N}$, let $C_n$ be the set of fixed points of $f_n$, i.e., the set of $x \in C$ such that $f_n(x) = x$. Since $f_n$ is continuous and affine, it follows easily that $C_n$ is closed and convex. For all $m, n \in \mathbb{N}$ and $x \in C_m$, we have $f_m f_n(x) = f_n f_m(x) = f_n(x)$, so $f_n(x) \in C_m$. Thus $f_n(C_m) \subseteq C_m$. For each $n \in \mathbb{N}$, put $C_n^* = \bigcap_{m<n} C_m$. Thus $C_n^*$ is also closed and convex, and we have $f_n(C_n^*) \subseteq C_n^*$.

We claim that $C_n^*$ is nonempty for all $n \in \mathbb{N}$. Since $C_n^*$ is a closed set in a compact metric space, the statement $C_n^* \neq \emptyset$ is $\Pi^0_1$ (theorem IV.1.7). Thus we can prove our claim by $\Pi^0_1$ induction on $n \in \mathbb{N}$. By assumption, $C_0^* = C$ is nonempty. If $C_n^*$ is nonempty, then by applying Schauder's fixed point theorem (IV.7.9) to $f_n \colon C_n^* \to C_n^*$, we see that $f_n$ has a fixed point in $C_n^*$, i.e., $C_{n+1}^* = C_n^* \cap C_n$ is nonempty. This gives the inductive step. Our claim is proved.

By Heine/Borel compactness of $C$ (theorem IV.1.5), we conclude that $\bigcap_{n \in \mathbb{N}} C_n$ is nonempty, i.e., there exists $x \in C$ such that $f_n(x) = x$ for all $n \in \mathbb{N}$. This proves the lemma. □

We need the following definition.

Definition IV.9.2 (subspaces, extensions). The following definitions are made in $\mathsf{RCA}_0$. Given a separable Banach space $\widehat{A}$, a *subspace* of $\widehat{A}$ consists of a separable Banach space $\widehat{S}$ together with a bounded linear mapping $\psi \colon \widehat{S} \to \widehat{A}$ such that $\|x\| = \|\psi(x)\|$ for all $x \in \widehat{S}$. We identify $x \in \widehat{S}$ with $\psi(x) \in \widehat{A}$. If $\widehat{B}$ is another separable Banach space and $F \colon \widehat{S} \to \widehat{B}$ is a bounded linear operator, we say that $\widetilde{F} \colon \widehat{A} \to \widehat{B}$ *extends* $F$ if $\widetilde{F}(x) = F(\psi(x))$ for all $x \in \widehat{S}$.

Given a separable Banach space $\widehat{A}$, a *bounded linear functional* on $\widehat{A}$ is a bounded linear operator $f \colon \widehat{A} \to \mathbb{R}$. The following is our $\mathsf{WKL}_0$ version of the Hahn/Banach theorem for separable Banach spaces.

Theorem IV.9.3 (Hahn/Banach theorem in $\mathsf{WKL}_0$). *The following is provable in* $\mathsf{WKL}_0$. *Let $\widehat{A}$ be a separable Banach space and let $\widehat{S}$ be a subspace of $\widehat{A}$. Let $f \colon \widehat{S} \to \mathbb{R}$ be a bounded linear functional such that $\|f\| \leq \alpha$, where $\alpha$ is a positive real number. Then there exists a bounded linear functional $\widetilde{f} \colon \widehat{A} \to \mathbb{R}$ extending $f$ such that $\|\widetilde{f}\| \leq \alpha$.*

PROOF. We may safely assume that $\alpha = 1$.

Let $A = \{a_i : i \in \mathbb{N}\}$ and $S = \{s_i : i \in \mathbb{N}\}$. We may safely assume that $a_0 = s_0 = 0$. Let $C_0$ be the closed convex set in $\mathbb{R}^{\mathbb{N}}$ consisting of those sequences $\langle z_i : i \in \mathbb{N}\rangle$ such that $z_0 = 0$ and $|z_i - z_j| \leq \|a_i - a_j\|$ for all $i, j \in \mathbb{N}$. $C_0$ is included in the compact product space

$$\prod_{i\in\mathbb{N}} [-\|a_i\|, \|a_i\|]$$

(cf. lemma III.2.5).

To each $z = \langle z_i : i \in \mathbb{N}\rangle \in C_0$ is associated a continuous function

$$g = g_z : \widehat{A} \to \mathbb{R}$$

such that $g(a_i) = z_i$ for all $i \in \mathbb{N}$. Namely, the code $G$ of $g$ is given by putting $(a_i, r)G(b, s)$ if and only if $r + |b - z_i| < s$. Thus we shall identify points of $C_0$ with continuous functions $g : \widehat{A} \to \mathbb{R}$ satisfying

$$|g(x) - g(x')| \leq \|x - x'\|$$

for all $x, x' \in \widehat{A}$.

Let $C_1 = \{g \in C_0 : g(\psi(s)) = f(s) \text{ for all } s \in \widehat{S}\}$. Clearly $C_1$ is a compact convex subset of $C_0$. We claim that $C_1$ is nonempty. To see this, note that $C_1 = \bigcap_{k\in\mathbb{N}} C_{1,k}$ where

$$C_{1,k} = \{g \in C_0 : g(\psi(s_j)) = f(s_j) \text{ for all } j \leq k\}.$$

Thus, by Heine/Borel compactness (theorem IV.1.5), it suffices to show $C_{1,k} \neq \emptyset$ for all $k \in \mathbb{N}$. Putting $g(x) = \min_{j\leq k}(f(s_j) + \|x - \psi(s_j)\|)$, it is straightforward to check that $g \in C_{1,k}$. This proves our claim.

Next let

$$C_2 = \{g \in C_1 : g(x + \psi(s)) = g(x) + g(\psi(s)) \text{ for all } x \in \widehat{A} \text{ and } s \in \widehat{S}\}.$$

Clearly $C_2$ is a compact convex subset of $C_1$. Note that $C_2$ is the set of common fixed points of the maps $T_j : C_1 \to C_1$, $j \in \mathbb{N}$, given by

$$(T_j g)(x) = g(x + \psi(s_j)) - g(\psi(s_j)).$$

It is also straightforward to verify that $T_j$, $j \in \mathbb{N}$, is a commuting sequence of continuous affine maps from $C_1$ to $C_1$. Hence by lemma IV.9.1 we have $C_2 \neq \emptyset$.

Finally let

$$C_3 = \{g \in C_2 : g(x + y) = g(x) + g(y) \text{ for all } x, y \in \widehat{A}\}.$$

Clearly $C_3$ is a compact convex subset of $C_2$. Note that $C_3$ is the set of common fixed points of the maps $U_j : C_2 \to C_2$, $j \in \mathbb{N}$, given by

$$(U_j g)(x) = g(x + a_j) - g(a_j).$$

It is straightforward to verify that $U_j$, $j \in \mathbb{N}$, is a commuting sequence of continuous affine maps from $C_2$ to $C_2$. Hence by lemma IV.9.1 we have $C_3 \neq \emptyset$.

For any $g \in C_3$, we have $g(nx) = ng(x)$ for all $n \in \mathbb{N}$ and $x \in \widehat{A}$. Hence

$$ng\left(\frac{m}{n}x\right) = g(mx) = mg(x)$$

for all $m, n \geq 1$. Hence $g(qx) = qg(x)$ for all $q \in \mathbb{Q}$. From this it follows that $g(\alpha x) = \alpha g(x)$ for all $\alpha \in \mathbb{R}$ and $x \in \widehat{A}$. Thus any $g \in C_3$ is a bounded linear functional on $\widehat{A}$ extending $f$. This completes the proof. □

We now turn to the reversal of the previous theorem. We shall show that the separable Hahn/Banach theorem is equivalent to $\mathsf{WKL}_0$ over $\mathsf{RCA}_0$.

Theorem IV.9.4 (reversal). *The separable Hahn-Banach theorem* (*as stated in theorem* IV.9.3) *is equivalent over* $\mathsf{RCA}_0$ *to weak König's lemma.*

Proof. Theorem IV.9.3 tells us that weak König's lemma implies the separable Hahn/Banach theorem. For the converse, we reason in $\mathsf{RCA}_0$ and assume the separable Hahn/Banach theorem. Instead of proving weak König's lemma directly, we shall prove $\Sigma^0_1$ separation (lemma IV.4.4.2).

Let $\varphi(n, i)$ be a $\Sigma^0_1$ formula such that $\neg\exists n(\varphi(n, 0) \wedge \varphi(n, 1))$. Write $\varphi(n, i)$ as $\exists m\, \theta(m, n, i)$ where $\theta$ is $\Sigma^0_0$. Define

$$\delta_{mn} = \begin{cases} 2^{-k} & \text{if } k = (\text{least } j \leq m)\, \theta(j, n, 0), \\ -2^{-k} & \text{if } k = (\text{least } j \leq m)\, \theta(j, n, 1), \\ 0 & \text{otherwise,} \end{cases}$$

and let $\delta_n = \langle \delta_{mn} : m \in \mathbb{N} \rangle$. Note that $\delta_n$ is a real number. For $(p, q) \in \mathbb{Q} \times \mathbb{Q}$, let

$$\|(p, q)\|_{mn} = \begin{cases} \max\left(\left|\dfrac{1 - \delta_{mn}}{1 + \delta_{mn}} p + q\right|, |p - q|\right) & \text{if } \delta_{mn} > 0, \\ \max\left(\left|\dfrac{1 + \delta_{mn}}{1 - \delta_{mn}} p - q\right|, |p + q|\right) & \text{if } \delta_{mn} < 0, \\ \max(|p + q|, |p - q|) & \text{if } \delta_{mn} = 0. \end{cases}$$

Let $\|(p, q)\|_n = \langle \|(p, q)\|_{mn} : m \in \mathbb{N} \rangle$ and note that $\|(p, q)\|_n$ is a real number.

Let $A$ be the set of (codes for) finite nonempty sequences of elements of $\mathbb{Q} \times \mathbb{Q}$. Define addition and scalar multiplication on $A$ in the obvious way so as to make $A$ a vector space over $\mathbb{Q}$ (cf. §II.10). For $\langle (p_i, q_i) : i \leq n \rangle \in A$, define

$$\|\langle (p_i, q_i) : i \leq n \rangle\| = \sum_{i=0}^{n} 2^{-i-1} \cdot \|(p_i, q_i)\|_i.$$

Let $\widehat{A}$ be the separable Banach space coded by $A$ with this norm.

Intuitively, $\widehat{A}$ is the $\ell_1$-sum of separable Banach spaces $\widehat{A}_n$ where, for each $n \in \mathbb{N}$, $\widehat{A}_n$ is the 2-dimensional Banach space $\mathbb{R} \times \mathbb{R}$ with unit ball determined by $\delta_n$. The various cases are:

1. $\delta_n > 0$. Here the unit ball is the parallelogram with vertices $(0,1)$, $(0,-1)$, $(-1-\delta_n, -\delta_n)$ and $(1+\delta_n, \delta_n)$.
2. $\delta_n < 0$. Here the unit ball is the parallelogram with vertices $(0,1)$, $(0,-1)$, $(-1+\delta_n, -\delta_n)$ and $(1-\delta_n, \delta_n)$.
3. $\delta_n = 0$. Here the unit ball is the parallelogram with vertices $(0,1)$, $(0,-1)$, $(-1,0)$ and $(1,0)$.

Let $S$ be the set of (codes for) finite nonempty sequences of pairs of rational numbers of the form $(p,0)$. $S$ is a subset of $A$ and so inherits the addition, scalar multiplication, and norm described above. Let $\widehat{S}$ be the separable Banach space coded by $S$ and note that $\widehat{S}$ is a subspace of $\widehat{A}$. Intuitively, $\widehat{S}$ is the $\ell_1$-sum of the $x$-axes of the 2-dimensional spaces $\widehat{A}_n$, $n \in \mathbb{N}$.

Let $f : S \to \mathbb{R}$ be defined by

$$f(\langle (p_0,0), \ldots, (p_n,0)\rangle) = \sum_{i=0}^{n} 2^{-i-1} \cdot p_i.$$

Note that $f$ is linear on $S$, and

$$\begin{aligned} |f(\langle (p_0,0), \ldots, (p_n,0)\rangle)| &= \left| \sum_{i=0}^{n} 2^{-i-1} \cdot p_i \right| \\ &\leq \sum_{i=0}^{n} 2^{-i-1} \cdot |p_i| \\ &\leq \sum_{i=0}^{n} 2^{-i-1} \cdot \|(p_i,0)\|_i \\ &= \|\langle (p_0,0), \ldots, (p_n,0)\rangle\|. \end{aligned}$$

Thus $f$ encodes a bounded linear functional on $\widehat{S}$ with $\|f\| \leq 1$ (cf. definition II.10.5).

Now apply the separable Hahn/Banach theorem to obtain an extension $\widetilde{f}$ of $f$ to $\widehat{A}$ with $\|\widetilde{f}\| \leq 1$.

For $n \in \mathbb{N}$ let $z_n \in A$ be the sequence of length $n+1$ of the form $\langle (0,0), \ldots, (0,0), (0,1)\rangle$. Note that

$$|\widetilde{f}(z_n)| \leq \|z_n\| = 2^{-n-1}.$$

Moreover, if $\delta_n > 0$, then we have

$$\begin{aligned} |2^{-n-1}(1+\delta_n) + \delta_n \widetilde{f}(z_n)| &= |\widetilde{f}(\langle (0,0), \ldots, (0,0), (1+\delta_n, \delta_n)\rangle)| \\ &\leq \|\langle (0,0), \ldots, (0,0), (1+\delta_n, \delta_n)\rangle\| \\ &= 2^{-n-1}, \end{aligned}$$

which implies $\widetilde{f}(z_n) = -2^{-n-1}$. Similarly, if $\delta_n < 0$, then $\widetilde{f}(z_n) = 2^{-n-1}$.

With this in mind, let $\widetilde{f}(z_n) = \langle \widetilde{f}(z_n)_k : k \in \mathbb{N} \rangle$ (viewed as a sequence of rational numbers; cf. the definition of real numbers in §II.4). By $\Delta^0_1$ comprehension, let $X = \{n \in \mathbb{N} : \widetilde{f}(z_n)_{n+2} \leq 0\}$. Suppose that $\varphi(n, 0)$ holds. Then $\delta_n > 0$ and so $\widetilde{f}(z_n) = -2^{-n-1}$. Since

$$|\widetilde{f}(z_n) - \widetilde{f}(z_n)_{n+2}| \leq 2^{-n-2},$$

it follows that $\widetilde{f}(z_n)_{n+2} < 0$, hence $n \in X$. Similarly, if $\varphi(n, 1)$ holds, then $\delta_n < 0$, hence $\widetilde{f}(z_n) = 2^{-n-1}$, hence $\widetilde{f}(z_n)_{n+2} > 0$, hence $n \notin X$. Thus we have $\Sigma^0_1$ separation. By lemma IV.4.4, we have weak König's lemma. This completes the proof of the theorem. □

**Notes for §IV.9.** Theorems IV.9.3 and IV.9.4 are due to Brown/Simpson [27]. The proof of theorem IV.9.3 given here (using ideas of Kakutani) is essentially due to Shioji/Tanaka [219]. Lemma IV.9.1 is a variant of Shioji/Tanaka [219, theorem 7.1]. An even more elegant proof of theorem IV.9.3 is given in Humphreys/Simpson [128]. The fact that the separable Hahn/Banach theorem implies weak König's lemma (over $\mathsf{RCA}_0$) is due to Brown/Simpson [27], based on a recursive counterexample due to Bishop and Metakides/Nerode/Shore [188].

For more information on functional analysis in $\mathsf{RCA}_0$ and $\mathsf{WKL}_0$, see Brown [24], Brown/Simpson [27, 28], Humphreys [126], Humphreys/Simpson [127, 128], and §X.2 below.

## IV.10. Conclusions

In this chapter we have seen that several key mathematical theorems are provable in $\mathsf{WKL}_0$ and indeed equivalent to weak König's lemma over $\mathsf{RCA}_0$ in the sense of Reverse Mathematics. Among them are: the Heine/Borel theorem for $[0, 1]$ and for compact metric spaces (§IV.1); various properties of continuous real-valued functions on $[0, 1]$ and on compact metric spaces, including uniform continuity, the maximum principle, Riemann integrability, and Weierstraß approximation (§IV.2); the completeness and compactness theorems in mathematical logic (§IV.3), existence of real closure for countable formally real fields (§IV.4), uniqueness of algebraic closure of countable fields (§IV.5), existence of prime ideals in countable commutative rings (§IV.6), the Brouwer and Schauder fixed point theorems (§IV.7), the Peano existence theorem for solutions of ordinary differential equations (§IV.8), and the separable Hahn/Banach theorem (§IV.9).

Our principal technique for proving mathematical theorems in $\mathsf{WKL}_0$ has been to use compactness arguments of various kinds. For the reversals, we have made extensive use of $\Sigma^0_1$ separation (see lemma IV.4.4).

Chapter V

# ARITHMETICAL TRANSFINITE RECURSION

In §I.11 we introduced the formal system $\mathsf{ATR}_0$ of arithmetical transfinite recursion. We explained that $\mathsf{ATR}_0$ is much stronger than $\mathsf{ACA}_0$ from the viewpoint of mathematical practice and is of great importance with respect to Reverse Mathematics.

The purpose of this chapter is to present some details of results concerning mathematics and Reverse Mathematics in $\mathsf{ATR}_0$, which were merely outlined in §I.11. Models of $\mathsf{ATR}_0$ will be considered in later chapters; see especially §§VII.2–VII.3 and VIII.3–VIII.5.

## V.1. Countable Well Orderings; Analytic Sets

The purpose of this preliminary section is to present some basic definitions and results concerning countable well orderings. Our discussion of countable well orderings will be continued in §V.2 and concluded in §V.6.

In this section we shall introduce and use the notion of *analytic set*. Analytic sets (sometimes known in the literature as $\Sigma^1_1$ sets) are of fundamental importance in the branch of ordinary mathematics known as *classical descriptive set theory*. We shall investigate in §§V.3, V.4, and V.5 and in chapter VI the extent to which classical descriptive set theory can be developed formally within subsystems of second order arithmetic.

All of the results in this preliminary section will be proved within the relatively weak formal system $\mathsf{ACA}_0$, which was studied in chapter III. The stronger system $\mathsf{ATR}_0$, which is the main concern of the present chapter, will be introduced in §V.2.

Recall (from §II.3) that $\mathbb{N} \times \mathbb{N}$ is identified with a subset of $\mathbb{N}$ via the pairing function $(i, j) = (i + j)^2 + i$. We can use this identification to discuss binary relations on $\mathbb{N}$. A set $X \subseteq \mathbb{N} \times \mathbb{N} \subseteq \mathbb{N}$ is said to be *reflexive* if $\forall i\, \forall j\, ((i, j) \in X \to ((i, i) \in X \wedge (j, j) \in X))$. If $X$ is reflexive we write $\mathrm{field}(X) = \{i : (i, i) \in X\}$ and

$$i \leq_X j \leftrightarrow (i, j) \in X,$$
$$i <_X j \leftrightarrow ((i, j) \in X \wedge (j, i) \notin X).$$

DEFINITION V.1.1 (countable well orderings). The following definitions are made within $\mathsf{RCA}_0$. Let $X \subseteq \mathbb{N}$ be reflexive. We say that $X$ is *well founded* if it has no infinite descending sequence, i.e., there is no $f : \mathbb{N} \to \text{field}(X)$ such that $f(n+1) <_X f(n)$ for all $n \in \mathbb{N}$. We say that $X$ is a *countable linear ordering* if it is a reflexive linear ordering of its field, i.e.,

$$\forall i\, \forall j\, \forall k\, ((i \leq_X j \wedge j \leq_X k) \to i \leq_X k),$$
$$\forall i\, \forall j\, ((i \leq_X j \wedge j \leq_X i) \to i = j),$$
$$\forall i\, \forall j\, (i, j \in \text{field}(X) \to (i \leq_X j \vee j \leq_X i)).$$

We say that $X$ is a *countable well ordering* if it is both well founded and a countable linear ordering.

Let $\text{WF}(X)$, $\text{LO}(X)$, and $\text{WO}(X)$ be formulas saying that $X$ is respectively well founded, a countable linear ordering, and a countable well ordering. Clearly $\text{WO}(X)$ is a $\Pi^1_1$ formula with a single free variable, $X$. The main result of this section is theorem V.1.9 which says that the $\Pi^1_1$ formula $\text{WO}(X)$ is not equivalent to any $\Sigma^1_1$ formula.

An important tool is the *Kleene/Brouwer ordering*. Recall that Seq is the set of codes for finite sequences of natural numbers. We define KB to be the set of all pairs $(\sigma, \tau) \in \text{Seq} \times \text{Seq}$ such that either $\sigma \supseteq \tau$ (i.e., $\text{lh}(\sigma) \geq \text{lh}(\tau) \wedge \forall i\, (i < \text{lh}(\tau) \to \sigma(i) = \tau(i))$) or

$$\exists j < \min(\text{lh}(\sigma), \text{lh}(\tau))\, [\sigma(j) < \tau(j) \wedge \forall i < j\, (\sigma(i) = \tau(i))].$$

Thus $\leq_{\text{KB}}$ is a binary relation whose field is Seq. It is straightforward to verify (in $\mathsf{RCA}_0$ for instance) that $\leq_{\text{KB}}$ is a dense liner ordering with no left endpoint and with the empty sequence $\langle\rangle$ as its right endpoint.

DEFINITION V.1.2 (the Kleene/Brouwer ordering). The following definition is made in $\mathsf{RCA}_0$. Recall that a *tree* is a set $T \subseteq \text{Seq}$ such that $\forall \sigma\, \forall \tau\, ((\sigma \in \text{Seq} \wedge \sigma \subseteq \tau \wedge \tau \in T) \to \sigma \in T)$. We write $\text{KB}(T) = \text{KB} \cap (T \times T) =$ the restriction of $\leq_{\text{KB}}$ to $T$, i.e.,

$$\text{KB}(T) = \{(\sigma, \tau) \colon \sigma, \tau \in T \wedge \sigma \leq_{\text{KB}} \tau\}.$$

Thus $\text{KB}(T)$ is a linear ordering. We refer to $\text{KB}(T)$ as the *Kleene/Brouwer ordering of* $T$.

Recall that a *path* through a tree $T$ is a function $f : \mathbb{N} \to \mathbb{N}$ such that $\forall n\, (f[n] \in T)$, where $f[n] = \langle f(0), f(1), \ldots, f[n-1]\rangle$. The following lemma says that $T$ has a path if and only if $\text{KB}(T)$ is not a well ordering.

LEMMA V.1.3. *The following is provable in* $\mathsf{ACA}_0$. *Let* $T \subseteq \text{Seq}$ *be a tree. Then*

$$\text{WO}(\text{KB}(T)) \leftrightarrow \forall f\, \exists n\, (f[n] \notin T).$$

PROOF. If $f$ is a path through $T$, we have $f[n+1] \supsetneq f[n]$ hence $f[n+1] <_{\mathrm{KB}} f[n]$ for all $n$, so $\langle f[n] : n \in \mathbb{N}\rangle$ is a descending sequence witnessing that $\mathrm{KB}(T)$ is not a well ordering.

Conversely, suppose that $T$ is not well ordered under $\leq_{\mathrm{KB}}$. Let $\langle \sigma_m : m \in \mathbb{N}\rangle$ be a descending sequence, i.e., $\sigma_{m+1} <_{\mathrm{KB}} \sigma_m$ and $\sigma_m \in T$ for all $m \in \mathbb{N}$. Put $S = \{\sigma \in T : \exists m\, (\sigma \subseteq \sigma_m)\}$. The existence of $S$ is assured by arithmetical comprehension, and clearly $S$ is a subtree of $T$.

We claim that $S$ is finitely branching. Suppose not. Let $\sigma \in S$ be such that $\sigma^\frown\langle i\rangle \in S$ for infinitely many $i \in \mathbb{N}$. If $\sigma^\frown\langle i\rangle \in S$ let $f(i)$ be the least $m$ such that $\sigma^\frown\langle i\rangle \subseteq \sigma_m$. Then $i < j$ implies $\sigma_{f(i)} <_{\mathrm{KB}} \sigma_{f(j)}$ so $\{\sigma_{f(i)} : \sigma^\frown\langle i\rangle \in S\}$ is an infinite ascending sequence under $\leq_{\mathrm{KB}}$. This contradicts the fact that $\{\sigma_m : m \in \mathbb{N}\}$ is an infinite descending sequence. Our claim is proved.

Clearly $S$ is infinite so by König's lemma (a consequence of $\mathsf{ACA}_0$; see section III.7), $S$ has a path. Hence $T$ has a path. This completes the proof of lemma V.1.3. □

The next lemma is a formal version of the well known *Kleene normal form theorem* for $\Sigma^1_1$ relations.

LEMMA V.1.4 (normal form theorem). *Let $\varphi(X)$ be a $\Sigma^1_1$ formula. Then we can find an arithmetical (in fact $\Sigma^0_0$) formula $\theta(\sigma,\tau)$ such that $\mathsf{ACA}_0$ proves*

$$\forall X\, (\varphi(X) \leftrightarrow \exists f\, \forall m\, \theta(X[m], f[m])).$$

(Here $f$ ranges over total functions from $\mathbb{N}$ into $\mathbb{N}$. Also

$$X[m] = \langle \xi_0, \xi_1, \ldots, \xi_{m-1}\rangle$$

where $\xi_i = 1$ if $i \in X$, $0$ if $i \notin X$. Note that $\varphi(X)$ may contain free variables other than $X$. If this is the case, then $\theta(\sigma,\tau)$ will also contain those free variables.)

PROOF. Let us first prove the result under the assumption that $\varphi$ is arithmetical. In this special case we can write $\varphi$ in prenex normal form as

$$\forall m_1\, \exists n_1 \cdots \forall m_k\, \exists n_k\, \chi(X, m_1, n_1, \ldots, m_k, n_k)$$

where $\chi$ is quantifier-free and does not mention $X$ except in atomic formulas of the form $m_i \in X$, $n_i \in X$, $i = 1, \ldots, k$. (We can accomplish this by treating $+$ and $\cdot$ as ternary relation symbols instead of binary function symbols.) Given $X \subseteq \mathbb{N}$ we say that $g_i : \mathbb{N}^i \to \mathbb{N}$, $i = 1, \ldots, k$ are *Skolem functions for $X$* if

$$\forall m_1 \cdots \forall m_k\, \chi(X, m_1, g_1(m_1), \ldots, m_k, g_k(m_1, \ldots, m_k)).$$

From arithmetical comprehension it follows that $\varphi(X)$ holds if and only if there exist Skolem functions for $X$. Thus $\varphi(X)$ holds if and only if $\exists f\, \forall m\, \theta(X[m], f[m])$ where $\theta(X[m], f[m])$ is the following arithmetical

(in fact $\Sigma^0_0$) assertion: for all $m_1, \dots, m_k$ less than $m$, if $\langle 1, m_1\rangle$, $f(\langle 1, m_1\rangle)$, $\dots$, $\langle k, m_1, \dots, m_k\rangle$, $f(\langle k, m_1, \dots, m_k\rangle)$ are all less than $m$, then

$$\chi(X, m_1, f(\langle 1, m_1\rangle), \dots, m_k, f(\langle k, m_1, \dots, m_k\rangle))$$

holds. This proves lemma V.1.4 in the special case when $\varphi$ is arithmetical.

Suppose now that $\varphi$ is $\Sigma^1_1$. Let $\varphi(X) \equiv \exists Y\, \varphi'(X, Y)$ where $\varphi'$ is arithmetical. By the special case which was already proved, we have

$$\forall X\, \forall Y\, [\varphi'(X, Y) \leftrightarrow \exists f\, \forall m\, \theta'((X \oplus Y)[m], f[m])]$$

where $\theta'$ is arithmetical (in fact $\Sigma^0_0$) and

$$X \oplus Y = \{2n : n \in X\} \cup \{2n + 1 : n \in Y\}.$$

By a straightforward use of the pairing function we can convert $\theta'$ to another arithmetical (in fact $\Sigma^0_0$) formula $\theta$ such that

$$\forall X\, (\exists Y\, \exists f\, \forall m\, \theta'((X \oplus Y)[m], f[m]) \leftrightarrow \exists h\, \forall m\, \theta(X[m], h[m])).$$

This completes the proof of lemma V.1.4. □

One of the purposes of this book is to study the formalization of ordinary mathematics within subsystems of second order arithmetic. Accordingly, we shall now relate the previous lemma to the branch of ordinary mathematics known as *classical descriptive set theory*. An excellent textbook for this theory is Kechris [138]. The notion which we now require from classical descriptive set theory is that of *analytic set*. Of course we face the usual difficulty that $L_2$ (the language of second order arithmetic) is not powerful enough to discuss analytic sets directly. But, also as usual, there is no real loss since we can instead discuss *codes* for analytic sets. The appropriate codes are given by definitions V.1.5 and V.1.6 below.

As our underlying space for descriptive set theory, we choose the *Cantor space*. (Our reasons for this choice are explained in remark V.5.8, below.) When formalizing descriptive set theory in $L_2$, we shall often identify a set $X \subseteq \mathbb{N}$ with its characteristic function $X : \mathbb{N} \to \{0, 1\}$ given by $X(n) = 1$ if $n \in X$, 0 if $n \notin X$. Such a characteristic function will be called a *point of the Cantor space*. Thus each $X \subseteq \mathbb{N}$ is a point of the Cantor space, and conversely. We shall use $2^{\mathbb{N}}$ informally to denote the Cantor space (just as in §II.4 we used $\mathbb{R}$ informally to denote the space of all real numbers).

The following definitions are made in $\mathsf{RCA}_0$.

DEFINITION V.1.5 (analytic codes). An *analytic code* (i.e., a code for an analytic subset of the Cantor space $2^{\mathbb{N}}$) is a set $A \subseteq \mathrm{Seq}$ such that $A$ is a tree and each finite sequence $\sigma \in A$ is of the form $\sigma = \langle(\xi_0, m_0), \dots, (\xi_{k-1}, m_{k-1})\rangle$ where $\forall j < k\, (\xi_j \in \{0, 1\} \wedge m_j \in \mathbb{N})$. In other words, $\langle \xi_0, \dots, \xi_{k-1}\rangle \in 2^{<\mathbb{N}}$ and $\langle m_0, \dots, m_{k-1}\rangle \in \mathrm{Seq}$.

DEFINITION V.1.6 (analytic codes, continued). If $X \in 2^{\mathbb{N}}$ and $A$ is an analytic code, we say that $X$ *is a point of* $A$ (abbreviated $X \in A$) if

$\exists f\, \forall k\, A(X[k], f[k])$. Here $f$ ranges over total functions from $\mathbb{N}$ into $\mathbb{N}$, and we write $A(X[k], f[k])$ to mean that

$$\langle (X(0), f(0)), \ldots, (X(k-1), f(k-1)) \rangle \in A.$$

(There is a conflict here between the new notation $X \in A$ and the old notation $\sigma \in A$ of definition V.1.5. However, this conflict should cause no confusion since $X$ is a point of $2^{\mathbb{N}}$ while $\sigma \in$ Seq.) We abbreviate $\neg(X \in A)$ as $X \notin A$.

The following theorem (which is nothing but a reformulation of lemma V.1.4) says that analytic sets are in a sense the same thing as $\Sigma^1_1$ formulas. This theorem will be applied in §§V.3, V.5, and V.6.

Theorem V.1.7 (analytic codes and $\Sigma^1_1$ formulas). *For an analytic code $A$, the formula $X \in A$ is $\Sigma^1_1$. Conversely, for any $\Sigma^1_1$ formula $\varphi(X)$, $\mathsf{ACA}_0$ proves*

$$(\exists \text{ analytic code } A)\, \forall X\, (X \in A \leftrightarrow \varphi(X)).$$

Proof. It is obvious from definition V.1.6 that the formula $X \in A$ is $\Sigma^1_1$. For the converse, given a $\Sigma^1_1$ formula $\varphi(X)$, let $\theta(\sigma, \tau)$ be an arithmetical formula as provided by lemma V.1.4. Thus $\mathsf{ACA}_0$ proves $\forall X\, (\varphi(X) \leftrightarrow \exists f\, \forall j\, \theta(X[j], f[j]))$. By arithmetical comprehension, let $A$ be the set of all $\sigma \in$ Seq of the form $\sigma = \langle (\xi_0, m_0), \ldots, (\xi_{k-1}, m_{k-1}) \rangle$ such that $\forall j < k\, (\xi_j < 2)$ and

$$\forall j \le k\, \theta(\langle \xi_0, \ldots, \xi_{j-1} \rangle, \langle m_0, \ldots, m_{j-1} \rangle).$$

Clearly $A$ is a tree and has the other desired properties. □

The following uniform variant of theorem V.1.7 will sometimes be useful.

Theorem V.1.7′. For any $\Sigma^1_1$ formula $\varphi(n, X)$, $\mathsf{ACA}_0$ proves the existence of a sequence of analytic codes $\langle A_n : n \in \mathbb{N} \rangle$ such that $\forall n\, \forall X\, (\varphi(n, X) \leftrightarrow X \in A_n)$.

Proof. Lemma V.1.4 provides an arithmetical formula $\theta(n, \sigma, \tau)$ such that $\mathsf{ACA}_0$ proves $\forall n\, \forall X\, (\varphi(n, X) \leftrightarrow \exists f\, \forall j\, \theta(n, X[j], f[j]))$. Let $A$ be the set of all ordered pairs $(n, \langle (\xi_0, m_0), \ldots, (\xi_{k-1}, m_{k-1}) \rangle)$ such that $\forall j < k\, (\xi_j < 2)$ and

$$\forall j \le k\, \theta(n, \langle \xi_0, \ldots, \xi_{j-1} \rangle, \langle m_0, \ldots, m_{j-1} \rangle).$$

Then $A$ encodes the sequence $\langle A_n : n \in \mathbb{N} \rangle$ where $A_n = \{\sigma : (n, \sigma) \in A\}$. This sequence has the desired properties. □

We now relate the notion of analytic code to the Kleene/Brouwer ordering. Given an analytic code $A$ and a point $X \in 2^{\mathbb{N}}$, put

$$\mathrm{T}_A(X) = \{\tau \in \text{Seq} : A(X[\mathrm{lh}(\tau)], \tau)\}.$$

Thus $\mathrm{T}_A(X)$ is a tree, and $X \in A$ holds if and only if $\mathrm{T}_A(X)$ has a path. Combining the previous results, we obtain:

LEMMA V.1.8. *For any* $\Pi^1_1$ *formula* $\psi(X)$, $\mathsf{ACA}_0$ *proves the existence of an analytic code* $A$ *such that*

$$\forall X\,(\psi(X) \leftrightarrow \mathrm{WO}(\mathrm{KB}(\mathrm{T}_A(X)))).$$

PROOF. Let $\varphi(X)$ be the $\Sigma^1_1$ formula $\neg\psi(X)$. By theorem V.1.7 we get an analytic code $A$ such that $\forall X\,(\varphi(X) \leftrightarrow X \in A)$. Thus $\forall X\,(\psi(X) \leftrightarrow \mathrm{T}_A(X)$ has no path). By lemma V.1.3 we get $\forall X\,(\psi(X) \leftrightarrow \mathrm{WO}(\mathrm{KB}(\mathrm{T}_A(X))))$. This completes the proof. □

The above lemma may be interpreted as saying that the $\Pi^1_1$ formula $\mathrm{WO}(X)$ is in a sense "universal" $\Pi^1_1$, provably in $\mathsf{ACA}_0$. We are now ready to prove the next theorem, which says that $\mathrm{WO}(X)$ is not equivalent to any $\Sigma^1_1$ formula, again provably in $\mathsf{ACA}_0$.

THEOREM V.1.9. *For any* $\Sigma^1_1$ *formula* $\varphi(X)$, $\mathsf{ACA}_0$ *proves*

$$\neg\forall X\,(\varphi(X) \leftrightarrow \mathrm{WO}(X)).$$

PROOF. We reason in $\mathsf{ACA}_0$. Suppose by way of contradiction that $\forall X\,(\varphi(X) \leftrightarrow \mathrm{WO}(X))$ where $\varphi(X)$ is $\Sigma^1_1$. We diagonalize by putting $\psi(X) \equiv (X$ is an analytic code and $\neg\varphi(\mathrm{KB}(\mathrm{T}_X(X))))$. Since $\psi(X)$ is $\Pi^1_1$, lemma V.1.8 provides an analytic code $A$ such that $\forall X\,(\psi(X) \leftrightarrow \mathrm{WO}(\mathrm{KB}(\mathrm{T}_A(X)))$. Thus $\psi(A)$ if and only if $\neg\psi(A)$. This contradiction completes the proof. □

We shall now reformulate the previous theorem in the terminology of analytic sets. A well known theorem of classical descriptive set theory, due to Lusin and Sierpinski, says that the set of all countable well orderings is not analytic. We shall now show that this theorem is provable in $\mathsf{ACA}_0$.

THEOREM V.1.10. *The following is provable in* $\mathsf{ACA}_0$. *There is no analytic code* $A$ *such that*

$$\forall X\,(X \in A \leftrightarrow \mathrm{WO}(X)).$$

PROOF. This is equivalent to theorem V.1.9 in view of theorem V.1.7. □

There is a stronger theorem (also due to Lusin and Sierpinski) which reads as follows. *Let* $A$ *be an analytic set of countable well orderings*; *then the order types of the well orderings in* $A$ *are bounded by some countable ordinal*. This is known as the $\Sigma^1_1$ *bounding principle*. We shall see (in §V.6) that this theorem is not provable in $\mathsf{ACA}_0$ but is provable in the stronger formal system $\mathsf{ATR}_0$. We shall also see (in §§V.3, V.4, and V.5) that many other theorems of classical descriptive set theory are not provable in $\mathsf{ACA}_0$ but are provable in $\mathsf{ATR}_0$.

We end the section with some exercises.

EXERCISE V.1.11. Show that $\mathsf{ACA}_0$ is equivalent over $\mathsf{RCA}_0$ to the assertion that for all trees $T \subseteq \mathrm{Seq}$, $\mathrm{WO}(\mathrm{KB}(T)) \leftrightarrow \forall f\,\exists n\, f[n] \notin T$.

Hint: The forward direction is given by lemma V.1.3. For the reversal, use a tree as in the proof of theorem III.7.2.

EXERCISES V.1.12. Let $A_n$, $n \in \mathbb{N}$, be a sequence of analytic codes.

1. Prove in $\mathsf{RCA}_0$ that there exists an analytic code $A'$ such that
$$\forall X\,(X \in A' \leftrightarrow \exists n\,(X \in A_n)).$$
2. Prove in $\Sigma^1_1$-$\mathsf{AC}_0$ that there exists an analytic code $A''$ such that
$$\forall X\,(X \in A'' \leftrightarrow \forall n\,(X \in A_n)).$$
3. Prove in $\mathsf{RCA}_0$ that there exists an analytic code $A^*$ such that
$$\forall n\,\forall X\,(\{n\} \cup \{n+m+1 : m \in X\} \in A^* \leftrightarrow X \in A_n).$$

Note: These analytic codes are denoted $A' = \bigcup_{n\in\mathbb{N}} A_n$, $A'' = \bigcap_{n\in\mathbb{N}} A_n$, $A^* = \bigoplus_{n\in\mathbb{N}} A_n$ respectively.

**Notes for §V.1.** For background on descriptive set theory, including analytic sets and the Kleene/Brouwer ordering, see Kechris [138], Mansfield/Weitkamp [171], Moschovakis [191], and Rogers [208]. The result stated in exercise V.1.11 is due to Hirst [121].

## V.2. The Formal System $\mathsf{ATR}_0$

The purpose of this section is to introduce the formal system $\mathsf{ATR}_0$ and to illustrate some of the proof techniques which are available in it. (Another important proof technique, the method of pseudohierarchies, will be introduced in §V.4.)

The acronym ATR stands for *arithmetical transfinite recursion*. Before discussing arithmetical transfinite recursion, we shall first discuss a related but much weaker principle known as *arithmetical transfinite induction*.

In ordinary mathematics, a fundamental property of countable well orderings is that proofs by transfinite induction may be carried out along them. In other words, if we have a countable well ordering $X$ and we are trying to prove that some property $\varphi(j)$ holds for each $j \in \mathrm{field}(X)$, we may legitimately assume that $\varphi(i)$ holds for all $i <_X j$. We now point out that this procedure is formally valid in $\mathsf{ACA}_0$ provided $\varphi(j)$ is arithmetical. In other words:

LEMMA V.2.1 (arithmetical transfinite induction). *For any arithmetical formula $\varphi(j)$, $\mathsf{ACA}_0$ proves*
$$(\mathrm{WO}(X) \wedge \forall j\,(\forall i\,(i <_X j \to \varphi(i)) \to \varphi(j))) \to \forall j\,\varphi(j).$$

PROOF. By arithmetical comprehension, let $Y$ be the set of all $j$ such that $\neg\varphi(j)$. By hypothesis we have that for all $j \in Y$ there exists $i \in Y$ such that $i <_X j$. If $Y$ is nonempty, define $f : \mathbb{N} \to Y$ by $f(0) =$ least $j \in Y$; $f(n+1) =$ least $i \in Y$ such that $i <_X f(n)$. Thus $f$ is a descending sequence through $X$, contradicting the assumption $\mathrm{WO}(X)$. Hence $Y$ is empty, i.e., $\forall j\,\varphi(j)$. □

The above lemma says that arithmetical transfinite induction is provable in $\mathsf{ACA}_0$. Having made this preliminary remark, we now turn to the discussion of arithmetical transfinite recursion. It will become clear that arithmetical transfinite recursion (unlike arithmetical transfinite induction) is very much stronger than $\mathsf{ACA}_0$.

The idea of arithmetical transfinite recursion is as follows. Suppose we are given a countable well ordering $X$ and an arithmetical formula $\theta(n, Y)$. To each $j \in \text{field}(X)$ we wish to associate a set $Y_j$. We define the $Y_j$'s by transfinite recursion along $X$. Assume that $Y_i$ has already been defined for each $i <_X j$. Then we define

$$Y^j = \{(m, i) : i <_X j \wedge m \in Y_i\}$$

and

$$Y_j = \{n : \theta(n, Y^j)\}.$$

Intuitively, $Y^j$ is the cumulative result of comprehension by $\theta$ applied repeatedly along $X$ up to (but not including) $j$. Then $Y_j$ is the result of applying $\theta$ one more time.

In accordance with the above informal description, we make the following formal definition.

DEFINITION V.2.2. Let $\theta(n, Y)$ be any formula. Define $\mathrm{H}_\theta(X, Y)$ to be the formula which says that $\mathrm{LO}(X)$ and that $Y$ is equal to the set of all pairs $(n, j)$ such that $j \in \text{field}(X)$ and $\theta(n, Y^j)$ where $Y^j = \{(m, i) : i <_X j \wedge (m, i) \in Y\}$. Intuitively $\mathrm{H}_\theta(X, Y)$ says that $Y$ is the result of iterating $\theta$ along $X$. We also define $\mathrm{H}_\theta(k, X, Y)$ to be the formula which says that $\mathrm{LO}(X)$ and $k \in \text{field}(X)$ and $Y$ is equal to the set of all pairs $(n, j)$ as above such that in addition $j <_X k$. Intuitively $\mathrm{H}_\theta(k, X, Y)$ says that $Y = Y^k =$ the result of iterating $\theta$ along $X$ up to $k$. Thus $\mathrm{H}_\theta(X, Y)$ and $k \in \text{field}(X)$ imply $\mathrm{H}_\theta(k, X, Y^k)$.

(Note that $\theta(n, Y)$ may contain free variables other than those displayed. If this is the case, then $\mathrm{H}_\theta(X, Y)$ and $\mathrm{H}_\theta(k, X, Y)$ will also contain those free variables. Note also that if $\theta(n, Y)$ is arithmetical, then so is $\mathrm{H}_\theta(X, Y)$.)

LEMMA V.2.3. *The following is provable in* $\mathsf{ACA}_0$. *Let* $\mathrm{WO}(X)$ *be assumed. Then there is at most one* $Y$ *such that* $\mathrm{H}_\theta(X, Y)$. *Also, for each* $k$, *there is at most one* $Y$ *such that* $\mathrm{H}_\theta(k, X, Y)$.

PROOF. Suppose $\mathrm{WO}(X)$ and $\mathrm{H}_\theta(X, Y)$ and $\mathrm{H}_\theta(X, Z)$. We shall show that $Y^j = Z^j$ for all $j$, by arithmetical transfinite induction (lemma V.2.1). By the induction hypothesis we may assume that $Y^i = Z^i$ for all $i <_X j$. Then $Y_i = \{m : \theta(m, Y^i)\} = \{m : \theta(m, Z^i)\} = Z_i$. Hence $Y^j = \{(m, i) : i <_X j \wedge m \in Y_i\} = \{(m, i) : i <_X j \wedge m \in Z_i\} = Z^j$. By arithmetical transfinite induction we have $Y^j = Z^j$ for all $j$. It follows

easily that $Y = Z$. This completes the proof of the first part. The proof of the second part is similar. □

We now define the formal system of arithmetical transfinite recursion, $\mathsf{ATR}_0$.

Definition V.2.4 (definition of $\mathsf{ATR}_0$). $\mathsf{ATR}_0$ is the formal system in the language of second order arithmetic whose axioms consist of $\mathsf{ACA}_0$ plus all instances of

$$\forall X\,(\mathrm{WO}(X) \to \exists Y\,\mathrm{H}_\theta(X, Y))$$

where $\theta$ is arithmetical.

The system $\mathsf{ATR}_0$ is properly stronger than $\mathsf{ACA}_0$. To see this, consider the minimum $\omega$-model

$$\mathrm{ARITH} = \{Z \subseteq \omega\colon Z \text{ is arithmetical}\}$$

of $\mathsf{ACA}_0$ (§§I.3, III.1, VIII.1).

Proposition V.2.5. *The $\omega$-model* ARITH *is not a model of* $\mathsf{ATR}_0$.

Proof. Let $\theta(n, Y)$ be the arithmetical formula which says that $n \in \mathrm{TJ}(Y)$, i.e., $n$ is an element of the Turing jump of $Y$. Let $X$ be the canonical reflexive well ordering of $\mathbb{N}$, i.e., $X = \{(i, j)\colon i \leq j\}$. Then $\mathrm{WO}(X)$ holds and there exists a unique set $Y$ such that $\mathrm{H}_\theta(X, Y)$ holds. Namely $Y = \{(n, j)\colon n \in Y_j\}$ where $Y_j$ is the Turing jump of $Y^j = \{(m, i)\colon i < j \wedge m \in Y_i\}$. Thus $Y^j$ is essentially $\emptyset^{(j)}$, the $j$th Turing jump of the empty set. Thus $\mathrm{ARITH} = \{Z \subseteq \omega\colon \exists j\,(Z \text{ is recursive in } Y^j)\}$. Since $Y_j$ is the Turing jump of $Y^j$ and hence is not recursive in $Y^j$, it follows that $Y \notin \mathrm{ARITH}$. (Another way to see this is to observe that $Y = \emptyset^{(\omega)} =$ essentially the truth set for first order arithmetic. Hence $Y \notin$ ARITH by Tarski's theorem on the undefinability of truth.) Thus for this particular $X$ and $\theta$ we have $\mathrm{ARITH} \models (\mathrm{WO}(X) \wedge \neg\exists Y\,\mathrm{H}_\theta(X, Y))$. So ARITH is not a model of $\mathsf{ATR}_0$. □

For those readers who happen to be familiar with hyperarithmetical sets (see also §VIII.3), we point out the following:

Proposition V.2.6. *The $\omega$-model*

$$\mathrm{HYP} = \{Z \subseteq \omega\colon Z \text{ is hyperarithmetical}\}$$

*is not a model of* $\mathsf{ATR}_0$.

Proof. Let $\theta(n, Y)$ say that $n$ belongs to the Turing jump of $Y$. Let $X$ be a *recursive pseudowellordering*, i.e., a recursive linear ordering which has infinite descending sequences but no hyperarithmetical infinite descending sequences. Thus $\mathrm{H}_\theta(X, Y)$ says that $Y$ is what is sometimes known as a pseudohierarchy on $X$ (compare §V.4). By lemma VIII.3.23 (see also Harrison [106]), there is no hyperarithmetical $Y$ such that $\mathrm{H}_\theta(X, Y)$. Thus for this particular $X$ and $\theta$ we have $\mathrm{HYP} \models (\mathrm{WO}(X) \wedge \neg\exists Y\,\mathrm{H}_\theta(X, Y))$. □

For more information on models of $\mathsf{ATR}_0$, see chapters VII and VIII of the present work, and also Simpson [234].

It will become clear in this chapter that the formal system $\mathsf{ATR}_0$ is much more powerful than $\mathsf{ACA}_0$ from the standpoint of ordinary mathematical practice. We shall see that many theorems of ordinary mathematics which are not provable in $\mathsf{ACA}_0$ are provable in $\mathsf{ATR}_0$. Among these theorems are: Lusin's theorem on Borel sets (§V.3), the perfect set theorem (every uncountable analytic set contains a perfect set, §V.4), determinacy of open games in Baire space (§V.8), the open Ramsey theorem (§V.9), and the Ulm structure theorem for countable reduced Abelian $p$-groups (§V.7). Furthermore, in accordance with our theme of Reverse Mathematics (§I.9), we shall obtain reversals showing that (special cases of) all of these theorems are in fact equivalent to $\mathsf{ATR}_0$ over a weak base theory. For example, the fact that every uncountable closed subset of the Cantor space contains a perfect set is equivalent to $\mathsf{ATR}_0$ over $\mathsf{ACA}_0$. Thus the axioms of $\mathsf{ATR}_0$ are necessary to prove the perfect set theorem, in the sense that no weaker axioms could possibly suffice. The same remark applies to each of the other theorems just mentioned.

Thus $\mathsf{ATR}_0$ plays a significant role with respect to the formalization of ordinary mathematics. A partial explanation for this phenomenon has to do with *countable ordinals*. Countable ordinals arise in a variety of contexts in ordinary mathematics. Sometimes they appear explicitly in the statement of a theorem (e.g., Ulm's theorem, or various properties of Borel sets). At other times they are involved overtly or covertly in the proof of a theorem. (This is the case with the open Ramsey theorem, for example.) It will turn out that $\mathsf{ATR}_0$ is the weakest set of axioms which permits the development of a decent theory of countable ordinals.

A countable ordinal is essentially an equivalence class of countable well orderings under the equivalence relation of isomorphism. The fundamental fact that the countable ordinals are linearly ordered depends on having sufficiently many *comparison maps*, i.e., isomorphisms, between countable well orderings. We shall now show that $\mathsf{ATR}_0$ proves the existence of the needed comparison maps. In §V.6 it will turn out that $\mathsf{ATR}_0$ is actually equivalent to the existence of these comparison maps.

Definition V.2.7 (comparison maps). The following definitions are made in $\mathsf{RCA}_0$. If $\mathrm{LO}(X)$ and $\mathrm{LO}(Y)$, we say that $X$ *is isomorphic to* $Y$ if there exists an isomorphism between them, i.e., a function $f : \mathrm{field}(X) \to \mathrm{field}(Y)$ such that $\forall i\, \forall j\, (i \leq_X j \leftrightarrow f(i) \leq_Y f(j))$ and $(\forall k \in \mathrm{field}(Y))\, (\exists i \in \mathrm{field}(X))\, (f(i) = k)$. We write $|X| = |Y|$ to mean that $X$ is isomorphic to $Y$. We write $f : |X| = |Y|$ to mean that $f$ is an isomorphism of $X$ onto $Y$.

We say that $X$ is an *initial section* of $Y$ if there exists $k \in \mathrm{field}(Y)$ such that $\forall i\, \forall j\, (i \leq_X j \leftrightarrow (i \leq_Y j \wedge j <_Y k))$. In this case we call $X$ the *initial section of* $Y$ *determined by* $k$.

We write $f : |X| < |Y|$ to mean that $f$ is an isomorphism of $X$ onto some initial section of $Y$. We write $f : |X| > |Y|$ to mean that $f$ is an isomorphism of some initial section of $X$ onto $Y$. The notations $|X| < |Y|$, $|X| > |Y|$, $f : |X| \leq |Y|$, $f : |X| \geq |Y|$, $|X| \leq |Y|$, and $|X| \geq |Y|$ are defined in the obvious way.

We say that $f$ is a *comparison map from $X$ to $Y$* if $f : |X| \leq |Y|$ or $f : |X| \geq |Y|$. We say that $X$ and $Y$ are *comparable* if there exists a comparison map from $X$ to $Y$.

LEMMA V.2.8 (uniqueness of comparison maps). *The following is provable in* $\mathsf{RCA}_0$. *If* $\mathrm{WO}(X)$ *and* $\mathrm{LO}(Y)$ *and $X$ and $Y$ are comparable, then the comparison map is unique.*

PROOF. We may restrict ourselves to the special case when $X$ and $Y$ are isomorphic. Given two isomorphisms $f : |X| = |Y|$ and $g : |X| = |Y|$, by $\Delta^0_1$ comprehension let $Z$ be the set of $m \in \mathrm{field}(X)$ such that $f(m) \neq g(m)$. Clearly for all $m \in Z$ there exists $n \in Z$ such that $n <_X m$. Thus, if $Z$ is nonempty, we can use primitive recursion (§II.3) to define $h : \mathbb{N} \to Z$ by $h(0) =$ any element of $Z$, $h(i+1) =$ least $n \in Z$ such that $n <_X h(i)$. Then $h$ is a descending sequence through $X$. This contradicts $\mathrm{WO}(X)$. Hence $Z$ is empty, i.e., $f = g$. □

LEMMA V.2.9 (comparability of countable well orderings). *It is provable in* $\mathsf{ATR}_0$ *that any two countable well orderings are comparable. In other words,* $\mathsf{ATR}_0$ *proves*

$$\forall W\, \forall X\, ((\mathrm{WO}(W) \wedge \mathrm{WO}(X)) \to (|W| \leq |X| \vee |W| \geq |X|)).$$

PROOF. Assume $\mathrm{WO}(W)$ and $\mathrm{WO}(X)$. Let $\theta(n, Y)$ say that $n \in \mathrm{field}(W)$ and $Y$ is an isomorphism of the initial section of $W$ determined by $n$ onto some initial section of $X$. Clearly $\theta$ is arithmetical, so by arithmetical transfinite recursion let $Y$ be such that $\mathrm{H}_\theta(X, Y)$ holds. Thus $(n, j) \in Y$ if and only if $Y^j$ is an isomorphism of the initial section of $W$ determined by $n$ onto some initial section of $X$. By arithmetical transfinite induction (lemma V.2.1), it follows straightforwardly that $Y$ is a comparison map between $W$ and $X$. □

DEFINITION V.2.10 (countable ordinals). Within $\mathsf{RCA}_0$ we define a *countable ordinal code* to be a countable well ordering (in the sense of definition V.1.1). Two countable ordinal codes $X$ and $Y$ are said to be *equal* (as countable ordinals) if $|X| = |Y|$. We use $\alpha, \beta, \gamma, \ldots$ as special variables ranging over countable ordinals. Thus $\alpha = |X|$ means that $X$ is a code for the countable ordinal $\alpha$. If $\alpha = |X|$ and $\beta = |Y|$ we write $\alpha < \beta$ to mean that $|X| < |Y|$, etc.

Lemma V.2.9 says that the countable ordinals (as just defined) form a linear ordering. In §V.6 we shall see that $\mathsf{ATR}_0$ is the weakest natural theory in which this can be proved. Thus we shall have a partial explanation

of why $\mathsf{ATR}_0$ is needed for the proofs of many ordinary mathematical theorems which depend (explicitly or implicitly) on countable ordinals.

**Notes for §V.2.** The system $\mathsf{ATR}_0$ was introduced by Friedman [68, 69] (see also Friedman [62, chapter II]) and Steel [256, chapter I]. Other key references on $\mathsf{ATR}_0$ are Friedman/McAloon/Simpson [76] and Simpson [234, 235, 247].

## V.3. Borel Sets

In this section and the next, we shall show that several basic theorems of classical descriptive set theory are provable in $\mathsf{ATR}_0$. The theorems in question concern Borel and analytic sets.

As our basic space for descriptive set theory we take the Cantor space, $2^{\mathbb{N}}$. As explained in §V.1, a point of the Cantor space is any set $X \subseteq \mathbb{N}$. Such a set is identified with its characteristic function $X : \mathbb{N} \to \{0,1\}$ where $X(n) = 1$ if $n \in X$, $0$ if $n \notin X$.

In §V.1 we introduced the appropriate codes for analytic sets (definitions V.1.5 and V.1.6). We now introduce codes for Borel sets.

DEFINITION V.3.1 (Borel codes). Within $\mathsf{RCA}_0$ we define a *Borel code* (i.e., a code for a Borel subset of $2^{\mathbb{N}}$) to be a set $B \subseteq \mathrm{Seq}$ such that $B$ is a tree, $B$ has no path, and there is exactly one $m \in \mathbb{N}$ such that $\langle m \rangle \in B$.

Let $\sigma \in B$ where $B$ is a Borel code. We say that $\sigma$ is an *interior node* of $B$ if $\exists n\,(\sigma^\frown\langle n\rangle \in B)$. Otherwise $\sigma$ is called an *end node* of $B$.

DEFINITION V.3.2 (evaluation maps). Given a Borel code $B$ and a point $X \in 2^{\mathbb{N}}$, an *evaluation map for $B$ at $X$* is defined in $\mathsf{RCA}_0$ to be a function $f : B \to \{0,1\}$ such that:

(i) if $\sigma$ is an end node of $B$, then

$$f(\sigma) = \begin{cases} 1 & \text{if } \sigma(\mathrm{lh}(\sigma)-1) = 2n+2+X(n), \\ 0 & \text{if } \sigma(\mathrm{lh}(\sigma)-1) = 2n+3-X(n), \\ 1 & \text{if } \sigma(\mathrm{lh}(\sigma)-1) = 1, \\ 0 & \text{if } \sigma(\mathrm{lh}(\sigma)-1) = 0; \end{cases}$$

(ii) if $\sigma$ is an interior node of $B$ and $\sigma \neq \langle\rangle$, then

$$f(\sigma) = \begin{cases} 1 & \text{if } \sigma(\mathrm{lh}(\sigma)-1) \text{ is odd and } \forall n\,(\sigma^\frown\langle n\rangle \in B \to f(\sigma^\frown\langle n\rangle) = 1), \\ 1 & \text{if } \sigma(\mathrm{lh}(\sigma)-1) \text{ is even and } \exists n\,(\sigma^\frown\langle n\rangle \in B \wedge f(\sigma^\frown\langle n\rangle) = 1), \\ 0 & \text{otherwise;} \end{cases}$$

(iii) $f(\langle\rangle) = f(\langle m\rangle)$ for the unique $m$ such that $\langle m\rangle \in B$.

In order to motivate the above definition, note that: (i) an end node corresponds to a subbasic open set $\{X \in 2^{\mathbb{N}} : X(n) = 1\}$, $\{X \in 2^{\mathbb{N}} : X(n) = 0\}$, $2^{\mathbb{N}}$, or $\emptyset$; (ii) an interior node other than $\langle\rangle$ corresponds to an operation of countable intersection or union. Intuitively, the class of Borel sets is the smallest class containing the subbasic neighborhoods (i) and closed under the operations (ii). This will become clearer in definition V.3.4 and lemma V.3.5.

Lemma V.3.3 (existence of evaluation maps). *The following is provable in* $\mathsf{ATR}_0$. *Given* $X \in 2^{\mathbb{N}}$ *and a Borel code* $B$, *there exists an evaluation map for* $B$ *at* $X$. *This evaluation map is unique.*

Proof. We reason in $\mathsf{ATR}_0$. Since $B$ has no path, the Kleene/Brouwer ordering $\mathrm{KB}(B)$ is a well ordering (definition V.1.2, lemma V.1.3). We define the desired evaluation map $f : B \to \{0, 1\}$ by means of arithmetical transfinite recursion (definition V.2.4) along $\mathrm{KB}(B)$. Uniqueness of $f$ is proved by arithmetical transfinite induction (lemma V.2.1) along $\mathrm{KB}(B)$.

The details of the recursion are as follows. We first write down an arithmetical formula $\theta(n, Y)$ which is virtually a transcription of definition V.3.2. Thus $\theta(n, Y)$ says: (i) if $\sigma$ is an end node of $B$ and $\sigma(\mathrm{lh}(\sigma) - 1) = 2m + 2 + X(m)$, then $n = 1$, etc.; (ii) if $\sigma \neq \langle\rangle$ is an interior node of $B$ and $\sigma(\mathrm{lh}(\sigma) - 1)$ is odd and $\forall m\, (\sigma^\frown\langle m\rangle \in B \to (1, \sigma^\frown\langle m\rangle) \in Y)$, then $n = 1$, etc.; and (iii) if $\sigma = \langle\rangle$ and $(1, \langle m\rangle) \in Y$ for some $m$, then $n = 1$, etc. Then, by arithmetical transfinite recursion along $\mathrm{KB}(B)$, there exists $Y$ such that $\mathrm{H}_\theta(\mathrm{KB}(B), Y)$. We set $f = \{(\sigma, n) : (n, \sigma) \in Y\}$. For each $\sigma \in B$ set $f^\sigma = \{(\tau, n) : \tau \leq_{\mathrm{KB}} \sigma \wedge (\tau, n) \in f\}$. By arithmetical transfinite induction along $\mathrm{KB}(B)$ it is straightforward to verify that $f^\sigma$ is a function from $\{\tau : \tau \leq_{\mathrm{KB}(B)} \sigma\}$ into $\{0, 1\}$ and that this function satisfies the clauses of definition V.3.2 up to $\sigma$. (Recall that $\sigma^\frown\langle m\rangle$ is strictly below $\sigma$ in Kleene/Brouwer ordering.) Thus $f$ is the desired evaluation map. Uniqueness of $f$ follows by lemma V.2.3 or can be proved directly by arithmetical transfinite induction along $\mathrm{KB}(B)$. □

Definition V.3.4. Within $\mathsf{ATR}_0$, given a point $X$ and a Borel code $B$, we write $\mathrm{E}(f, X, B)$ to mean that $f$ is an evaluation map for $B$ at $X$. Note that the formula $\mathrm{E}(f, X, B)$ is arithmetical (in the parameter $B$). We say that $X$ is a point of $B$ (abbreviated $X \in B$) if $\exists f\, (\mathrm{E}(f, X, B) \wedge f(\langle\rangle) = 1)$.

(This new notation $X \in B$ conflicts with the notation $\sigma \in B$ of definition V.3.2. However, no confusion should result, since $X \in 2^{\mathbb{N}}$ while $\sigma \in \mathrm{Seq}$.)

We say that $X \notin B$ if $\exists f\, (\mathrm{E}(f, X, B) \wedge f(\langle\rangle) = 0)$. By lemma V.3.3 we have $\forall X\, (X \notin B \leftrightarrow \neg(X \in B))$, provided of course that $B$ is a Borel code.

We now list some simple closure properties of the class of Borel subsets of the Cantor space $2^{\mathbb{N}}$. In the statement of the following lemma, $X$ ranges over points of $2^{\mathbb{N}}$.

LEMMA V.3.5. *The following facts are provable in* $\mathsf{ATR}_0$.

1. *There exist Borel codes* $B^0$ *and* $B^1$ *such that* $\forall X\,(X \notin B^0)$ *and* $\forall X\,(X \in B^1)$.
2. *For each* $n \in \mathbb{N}$ *and* $\xi \in \{0,1\}$ *there exists a Borel code* $B_n^\xi$ *such that* $\forall X\,(X \in B_n^\xi \leftrightarrow X(n) = \xi)$.
3. *Given a Borel code* $B$, *there exists a Borel code* $\overline{B}$ *such that* $\forall X\,(X \in \overline{B} \leftrightarrow X \notin B)$.
4. *Given a sequence of Borel codes* $\langle B_n : n \in \mathbb{N}\rangle$, *there exist Borel codes* $\bigcup_{n\in\mathbb{N}} B_n$ *and* $\bigcap_{n\in\mathbb{N}} B_n$ *such that*
$$\forall X\,(X \in \bigcup_{n\in\mathbb{N}} B_n \leftrightarrow \exists n\,(X \in B_n))$$
*and*
$$\forall X\,(X \in \bigcap_{n\in\mathbb{N}} B_n \leftrightarrow \forall n\,(X \in B_n)).$$
5. *Given a Borel code* $B$ *and a sequence of Borel codes* $\langle B_n : n \in \mathbb{N}\rangle$, *there exists a Borel code* $B'$ *such that* $\forall X\,(X \in B' \leftrightarrow X' \in B)$, *where*
$$X'(n) = \begin{cases} 1 & \text{if } X \in B_n, \\ 0 & \text{if } X \notin B_n. \end{cases}$$

PROOF.

1. $B^0 = \{\langle\rangle, \langle 0\rangle\}$; $B^1 = \{\langle\rangle, \langle 1\rangle\}$.
2. $B_n^\xi = \{\langle\rangle, \langle 2n+2+\xi\rangle\}$.
3. $\overline{B} = \{\overline{\sigma} : \sigma \in B\}$ where
$$\overline{\sigma}(i) = \begin{cases} \sigma(i)+1 & \text{if } \sigma(i) \text{ is even}, \\ \sigma(i)-1 & \text{if } \sigma(i) \text{ is odd}. \end{cases}$$
4. $$\bigcup_{n\in\mathbb{N}} B_n = \{\langle\rangle, \langle 0\rangle\} \cup \{\langle 0, n\rangle^\frown\tau : n \in \mathbb{N} \wedge \tau \in B_n\};$$
$$\bigcap_{n\in\mathbb{N}} B_n = \{\langle\rangle, \langle 1\rangle\} \cup \{\langle 1, n\rangle^\frown\tau : n \in \mathbb{N} \wedge \tau \in B_n\}.$$
5. $$\begin{aligned} B' = B \cup \{&\sigma^\frown\tau : \sigma \text{ is an end node of } B \\ &\text{and } \exists n\,(\sigma(\mathrm{lh}(\sigma)-1) = 2n+3 \wedge \tau \in B_n)\} \\ \cup\{&\sigma^\frown\tau : \sigma \text{ is an end node of } B \\ &\text{and } \exists n\,(\sigma(\mathrm{lh}(\sigma)-1) = 2n+2 \wedge \tau \in \overline{B_n})\}. \end{aligned}$$

It is straightforward to verify that these trees are Borel codes and have the desired properties. □

REMARK V.3.6 (properties of Borel sets). Intuitively, lemma V.3.5 says that: (1) $\emptyset$ and $2^\mathbb{N}$ are Borel sets; (2) the subbasic open sets $\{X \in 2^\mathbb{N} : X(n) = 0\}$ and $\{X \in 2^\mathbb{N} : X(n) = 1\}$ are Borel sets; the class of Borel

sets is closed under (3) complementation and (4) countable union and countable intersection; (5) for any Borel function $F\colon 2^{\mathbb{N}} \to 2^{\mathbb{N}}$ and Borel set $B \subseteq 2^{\mathbb{N}}$, the inverse image $F^{-1}(B)$ is Borel. (Here the function $F$ is given by $F(X) = X'$.) Whenever possible we shall identify these Borel sets with their codes as constructed in the proof of lemma V.3.5. In particular we shall denote by $\emptyset$, $2^{\mathbb{N}}$, and $\{X\colon X(n) = \xi\}$ the corresponding Borel codes $B^0$, $B^1$, and $B^\xi_n$.

The following lemma will be useful.

LEMMA V.3.7. *The following is provable in* $\mathsf{ATR}_0$. *Let* $\langle X_n\colon n \in \mathbb{N}\rangle$, $X_n \in 2^{\mathbb{N}}$, *be a sequence of points, and let* $\langle B_n\colon n \in \mathbb{N}\rangle$ *be a sequence of Borel codes. Then there exists a set* $Z \subseteq \mathbb{N}$ *such that* $\forall n\,(n \in Z \leftrightarrow X_n \in B_n)$.

PROOF. The proof of this lemma is similar to that of lemma V.3.3. Given any sequence of countable well orderings $\langle W_n\colon n \in \mathbb{N}\rangle$, we can form the sum

$$\sum_{n\in\mathbb{N}} W_n = \{((i,n),(j,n))\colon (i,j) \in W_n\} \cup \{((i,m),(j,n))\colon (i,i) \in W_m \wedge (j,j) \in W_n \wedge m < n\}.$$

Intuitively $\sum_{n\in\mathbb{N}} W_n$ consists of $W_0$ followed by $W_1$ followed by $\ldots$. Clearly $\sum_{n\in\mathbb{N}} W_n$ is a countable well ordering. In particular, taking $W_n = \mathrm{KB}(B_n)$, we see that $\sum_{n\in\mathbb{N}} \mathrm{KB}(B_n)$ is a countable well ordering. Using arithmetical transfinite recursion along $\sum_{n\in\mathbb{N}} \mathrm{KB}(B_n)$ we define a sequence of functions $\langle f_n\colon n \in \mathbb{N}\rangle$ and prove that $\forall n\,(f_n$ is an evaluation map for $B_n$ at $X_n)$. The details of this recursion are as for lemma V.3.3, so we omit them. Now by arithmetical comprehension let $Z = \{n\colon f_n(\langle\rangle) = 1\}$. Thus $Z = \{n\colon X_n \in B_n\}$. This completes the proof. □

A classical theorem of Souslin asserts that $\Delta^1_1 =$ Borel, i.e., every Borel set is $\Delta^1_1$ (i.e., both analytic and coanalytic) and conversely. There is a generalization known as *Lusin's separation theorem*, which reads as follows. Let $A_1$ and $A_0$ be disjoint $\Sigma^1_1$ (i.e., analytic) sets. Then there exists a Borel set $B$ such that $A_1 \subseteq B$ and $A_0 \cap B = \emptyset$.

We shall now show that these theorems of Souslin and Lusin are provable in $\mathsf{ATR}_0$. We begin with the "easy half" of Souslin's theorem.

THEOREM V.3.8. *The following is provable in* $\mathsf{ATR}_0$. *Given a Borel code* $B$, *there exist analytic codes* $A_1$ *and* $A_0$ *such that* $\forall X\,(X \in A_1 \leftrightarrow X \in B)$ *and* $\forall X\,(X \in A_0 \leftrightarrow X \notin B)$.

PROOF. By definition V.3.4 the formulas $X \in B$ and $X \notin B$ are $\Sigma^1_1$ (with parameter $B$). Hence by theorem V.1.7 there exist analytic codes $A_1$ and $A_0$ as desired. □

THEOREM V.3.9 (Lusin's theorem in $\mathsf{ATR}_0$). *Let* $A_1$ *and* $A_0$ *be analytic codes. If* $\neg\exists X\,(X \in A_1 \wedge X \in A_0)$ *then there exists a Borel code* $B$ *such that* $\forall X\,(X \in A_1 \to X \in B)$ *and* $\forall X\,(X \in A_0 \to X \notin B)$.

PROOF. Recall the definition of analytic codes (definition V.1.5). Without loss of generality, assume that $\langle\rangle \in A_0$ and $\langle\rangle \in A_1$. Let $T = A_1 * A_0 \subseteq \mathrm{Seq}$ be the set of all finite sequences of the form

$$\tau = \langle(\xi_0, m_0, n_0), \ldots, (\xi_{k-1}, m_{k-1}, n_{k-1})\rangle \qquad (*)$$

such that $\tau_1 \in A_1$ and $\tau_0 \in A_0$, where $\tau_1 = \langle(\xi_0, m_0), \ldots, (\xi_{k-1}, m_{k-1})\rangle$ and $\tau_0 = \langle(\xi_0, n_0), \ldots, (\xi_{k-1}, n_{k-1})\rangle$.

Clearly $T$ is a tree and $\langle\rangle \in T$. From the assumption $\neg\exists X\,(X \in A_1 \wedge X \in A_0)$ it follows that $T$ has no path. Hence the Kleene/Brouwer ordering $\mathrm{KB}(T)$ is a well ordering.

We use arithmetical transfinite recursion along $\mathrm{KB}(T)$ to define for each $\tau \in T$ a tree $B_\tau \subseteq \mathrm{Seq}$. These trees will turn out to be Borel codes. Assume that $\tau \in T$ and that $B_{\tau^\frown\langle(\xi,m,n)\rangle}$ has already been defined for each $(\xi, m, n)$ such that $\tau^\frown\langle(\xi, m, n)\rangle \in T$. We define $B_\tau$ as follows:

$$B_\tau = \bigcup_{\xi<2} \bigcup_{m\in\mathbb{N}} \bigcap_{\eta<2} \bigcap_{n\in\mathbb{N}} C_\tau^{\xi,m,\eta,n}$$

where

$$C_\tau^{\xi,m,\eta,n} = \begin{cases} B^\xi_{\mathrm{lh}(\tau)} (= \{X\colon X(\mathrm{lh}(\tau)) = \xi\}) & \text{if } \xi \neq \eta, \\ B_{\tau^\frown\langle(\xi,m,n)\rangle} & \text{if } \xi = \eta \text{ and } \tau^\frown\langle(\xi, m, n)\rangle \in T, \\ B^0 (= \emptyset) & \text{if } \xi = \eta \text{ and } \tau_1{}^\frown\langle(\xi, m)\rangle \notin A_1, \\ B^1 (= 2^{\mathbb{N}}) & \text{if } \xi = \eta \text{ and } \tau_1{}^\frown\langle(\xi, m)\rangle \in A_1 \\ & \qquad \text{and } \tau_0{}^\frown\langle(\xi, n)\rangle \notin A_0. \end{cases}$$

At each stage of the recursion we are applying the operations of countable union and countable intersection as defined in the proof of lemma V.3.5. (See lemma V.3.5 and remark V.3.6.)

We claim that for each $\tau \in T$, $B_\tau$ is a Borel code. The proof of this claim is by arithmetical transfinite induction along $\mathrm{KB}(T)$. Unfortunately the statement which is to be proved, "$B_\tau$ is a Borel code," is $\Pi^1_1$ rather than arithmetical. Thus there is a difficulty in showing that the tree $B_\tau$ has no path. We overcome this difficulty as follows. First, we note that $B_\tau$ consists of sequences of the form $\rho^\frown\sigma$ where $\mathrm{lh}(\rho) \leq 10$ and $\sigma \in B_{\tau^\frown\langle(\xi,m,n)\rangle}$ for some $\tau^\frown\langle(\xi, m, n)\rangle \in T$. Thus, by arithmetical transfinite recursion along $\mathrm{KB}(T)$, we can define for each $\tau \in T$ a function $g_\tau\colon B_\tau \to T$ such that $g_\tau(\langle\rangle) = \tau$, $g_\tau(\sigma_1) \subseteq g_\tau(\sigma_2)$ whenever $\sigma_1 \subseteq \sigma_2 \in B_\tau$, and $g_\tau(\sigma_1) \neq g_\tau(\sigma_2)$ whenever $\sigma_1 \subseteq \sigma_2 \in B_\tau$ with $\mathrm{lh}(\sigma_1) + 10 \leq \mathrm{lh}(\sigma_2)$. (We omit the details of this recursion.) Thus any path through $B_\tau$ would be mapped by $g_\tau$ to a path through $T$. Since $T$ has no path, it follows that $B_\tau$ has no path. Hence $B_\tau$ is a Borel code.

In particular we have a Borel code $B = B_{\langle\rangle}$. We shall now show that $B$ satisfies the conclusion of the theorem.

Let $X$ be given such that $X \in A_1$. By definition V.1.6 let $f : \mathbb{N} \to \mathbb{N}$ be such that $\forall k\,(\langle (X(j), f(j)) : j < k\rangle \in A_1)$. Let $S$ be the set of all $\tau \in T$ of the form $(*)$ such that $\forall j < k\,(\xi_j = X(j) \wedge m_j = f(j))$. Thus $S$ is a subtree of $T$. Hence $\mathrm{KB}(S)$ is a well ordering. We claim that $X \in B_\tau$ for each $\tau \in S$. The proof of this claim is by arithmetical transfinite induction along $\mathrm{KB}(S)$. (Unfortunately, the statement to be proved, "$X \in B_\tau$," is $\Delta^1_1$ rather than arithmetical. We overcome this difficulty as follows. By lemma V.3.7 let $Z$ be the set of $\tau \in T$ such that $X \in B_\tau$. Instead of proving that $X \in B_\tau$ for all $\tau \in S$, we shall prove an equivalent arithmetical assertion: $\tau \in Z$ for all $\tau \in S$. The proof is by arithmetical transfinite induction along $\mathrm{KB}(S)$.) Given $\tau \in S$, put $\xi = X(\mathrm{lh}(\tau))$ and $m = f(\mathrm{lh}(\tau))$. Let $\eta < 2$ and $n \in \mathbb{N}$ be arbitrary. If $\eta = 1 - \xi$ we have $X \in B^{\xi}_{\mathrm{lh}(\tau)} = C_\tau^{\xi,m,\eta,n}$. If $\eta = \xi$ and $\tau^\frown\langle(\xi, m, n)\rangle \in S$, we have $X \in B_{\tau^\frown\langle(\xi,m,n)\rangle} = C_\tau^{\xi,m,\eta,n}$ by induction hypothesis. If $\eta = \xi$ and $\tau^\frown\langle(\xi, m, n)\rangle \notin S$, we must have $\tau^\frown\langle(\xi, m, n)\rangle \notin T$. But clearly $\tau_1{}^\frown\langle(\xi, m)\rangle \in A_1$, so we must have $\tau_0{}^\frown\langle(\xi, n)\rangle \notin A_0$. Hence $X \in 2^{\mathbb{N}} = C_\tau^{\xi,m,\eta,n}$ in this case also. Thus $X \in \bigcap_{\eta<2}\bigcap_{n\in\mathbb{N}} C_\tau^{\xi,m,\eta,n}$. Hence $X \in B_\tau$. This completes the proof of our claim. In particular, taking $\tau = \langle\rangle$, we obtain $X \in B_{\langle\rangle} = B$.

The previous paragraph shows that $\forall X\,(X \in A_1 \to X \in B)$. A similar argument, which we omit, shows that $\forall X\,(X \in A_0 \to X \notin B)$.

This completes the proof of theorem V.3.9. □

As a corollary of theorem V.3.9 we obtain:

THEOREM V.3.10 (Souslin's theorem in $\mathsf{ATR}_0$). *If $A_1$ and $A_0$ are analytic codes such that $\forall X\,(X \in A_1 \leftrightarrow X \notin A_0)$, then there exists a Borel code $B$ such that $\forall X\,(X \in B \leftrightarrow X \in A_1)$. Conversely, given any Borel code $B$, there exist analytic codes $A_1$ and $A_0$ with these properties.*

PROOF. Immediate from theorems V.3.8 and V.3.9. □

The following uniform version of theorem V.3.9 will be used in the proof of theorem V.3.11.

THEOREM V.3.9′. The following is provable in $\mathsf{ATR}_0$. Let $\langle A^1_n : n \in \mathbb{N}\rangle$ and $\langle A^0_n : n \in \mathbb{N}\rangle$ be sequences of analytic codes such that $\neg\exists n\,\exists X\,(X \in A^1_n \wedge X \in A^0_n)$. Then there exists a sequence of Borel codes $\langle B_n : n \in \mathbb{N}\rangle$ such that $\forall n\,\forall X\,((X \in A^1_n \to X \in B_n) \wedge (X \in A^0_n \to X \notin B_n))$.

PROOF. For each $n$ let $T_n = A^1_n * A^0_n$ be as in the proof of theorem V.3.9. For each $n$, $\mathrm{KB}(T_n)$ is a well ordering. Hence the sum $\sum_{n\in\mathbb{N}} \mathrm{KB}(T_n)$ is a well ordering (see the proof of lemma V.3.7). By arithmetical transfinite recursion along $\sum_{n\in\mathbb{N}} \mathrm{KB}(T_n)$ define for each $(\tau, n)$ with $\tau \in T_n$ a Borel code $B^\tau_n$ as in the proof of theorem V.3.9. Setting $B_n = B^{\langle\rangle}_n$ we obtain a sequence of Borel codes $\langle B_n : n \in \mathbb{N}\rangle$ which has the desired properties. The details are as for theorem V.3.9. □

We end this section by pointing out that an interesting consequence of Lusin's separation theorem V.3.9 is also provable in $\mathsf{ATR}_0$. This consequence concerns Borel sets in the plane. Recall that $2^{\mathbb{N}} \times 2^{\mathbb{N}}$ is homeomorphic to $2^{\mathbb{N}}$ via the pairing function $(X, Y) \mapsto X \oplus Y$ where $(X \oplus Y)(2n) = X(n)$, $(X \oplus Y)(2n+1) = Y(n)$. Thus any Borel set $C \subseteq 2^{\mathbb{N}}$ may be regarded as a binary relation $C \subseteq 2^{\mathbb{N}} \times 2^{\mathbb{N}}$. Formally, if $C$ is a Borel code, we write $C(X, Y)$ to mean that $X \oplus Y \in C$.

THEOREM V.3.11 (Borel domain theorem in $\mathsf{ATR}_0$). *The following is provable in* $\mathsf{ATR}_0$. *The domain of any single-valued Borel relation is Borel. In other words, let $C$ be a Borel code such that*

$$\forall X\, (\exists \text{ at most one } Y)\, C(X, Y).$$

*Then there exists a Borel code $B$ such that*

$$\forall X\, (X \in B \leftrightarrow \exists Y\, C(X, Y)).$$

PROOF. By definition V.3.4 the formula $\exists Y\, C(X, Y)$ is $\Sigma^1_1$. By theorem V.1.7′ let $\langle A^1_n : n \in \mathbb{N}\rangle$ and $\langle A^0_n : n \in \mathbb{N}\rangle$ be sequences of analytic codes such that $\forall \xi\, \forall n\, \forall X\, (X \in A^\xi_n \leftrightarrow \exists Y\, (C(X, Y) \wedge Y(n) = \xi))$. From the hypothesis $\forall X\, (\exists \text{ at most one } Y)\, C(X, Y)$ it follows that $\neg \exists n\, \exists X\, (X \in A^1_n \wedge X \in A^0_n)$. Hence, by theorem V.3.9′, there exists a sequence of Borel codes $\langle B_n : n \in \mathbb{N}\rangle$ such that $\forall n\, \forall X\, (X \in A^1_n \to X \in B_n)$ and $\forall n\, \forall X\, (X \in A^0_n \to X \notin B_n)$. For each $X$ define $X'$ by $X'(n) = 1$ if $X \in B_n$, $0$ if $X \notin B_n$ (lemma V.3.7). From the hypothesis $\forall X\, (\exists \text{ at most one } Y)\, C(X, Y)$ it follows that $\forall X\, \forall Y\, (C(X, Y) \to Y = X')$. By lemma V.3.5.5, let $B$ be a Borel code such that $\forall X\, (X \in B \leftrightarrow C(X, X'))$. Then clearly $\forall X\, (X \in B \leftrightarrow \exists Y\, C(X, Y))$. This completes the proof. □

REMARK V.3.12. Our proof of Lusin's theorem in $\mathsf{ATR}_0$ made heavy use of arithmetical transfinite recursion. In §V.5 we shall obtain reversals showing that the use of arithmetical transfinite recursion (or of some equivalent set existence axiom) was essential here. Namely, both Lusin's theorem V.3.9 and its consequence, theorem V.3.11, are in an appropriate sense equivalent to $\mathsf{ATR}_0$. (Note: It can be shown that Souslin's theorem V.3.10 holds in the $\omega$-model HYP. Hence by proposition V.2.6 Souslin's theorem is not equivalent to $\mathsf{ATR}_0$.)

We end this section with some exercises.

EXERCISE V.3.13. A *coanalytic set* is defined to be the complement of an analytic set; see definition VI.2.3. Show that $\mathsf{ATR}_0$ proves the existence of two disjoint coanalytic sets which cannot be separated by a Borel set.

EXERCISE V.3.14. Show that the following strong converse of theorem V.3.11 is provable in $\mathsf{ATR}_0$. Any Borel set $B \subseteq 2^{\mathbb{N}}$ is the domain of a single-valued closed set $C \subseteq 2^{\mathbb{N}} \times \mathbb{N}^{\mathbb{N}}$.

Hint: Use lemma V.3.3.

EXERCISE V.3.15. Show that the following generalization of theorem V.3.11 is provable in $\mathsf{ATR}_0$. If $C \subseteq 2^{\mathbb{N}} \times 2^{\mathbb{N}}$ is Borel and if $\forall X\,(\exists$ at most countably many $Y)\,C(X, Y)$, then there exists a Borel set $B \subseteq 2^{\mathbb{N}}$ such that $\forall X\,(X \in B \leftrightarrow \exists Y\,C(X, Y))$.

EXERCISES V.3.16 (Borel uniformization). Let $B \subseteq 2^{\mathbb{N}} \times 2^{\mathbb{N}}$ be Borel. We say that $B$ is *Borel uniformizable* if there exists a Borel set $C \subseteq B$ such that $\forall X\,(\exists Y\,B(X, Y) \leftrightarrow \exists Y\,C(X, Y))$ and $\forall X\,(\exists$ at most one $Y)\,C(X, Y)$. Show that the following results are provable in $\mathsf{ATR}_0$.

1. If $\forall X\,(\{Y\colon B(X, Y)\}$ is countable), then $B$ is Borel uniformizable.
2. Same as 1 with "countable" replaced by "$\mathrm{K}_\sigma$". A $\mathrm{K}_\sigma$ set is the union of countably many compact sets.
3. Same as 1 with "countable" replaced by "non-meager".
4. Same as 1 with "countable" replaced by "of positive measure". Here we are referring to the fair coin measure, as in X.1.3.

**Notes for §V.3.** The results of this section are due to Simpson (previously unpublished).

## V.4. Perfect Sets; Pseudohierarchies

In this section we continue our investigation of the extent to which classical descriptive set theory can be formalized within $\mathsf{ATR}_0$. This investigation was begun in §§V.1 and V.3.

DEFINITION V.4.1 (perfect trees). Within $\mathsf{RCA}_0$, a finite sequence $\tau \in \mathbb{N}^{<\mathbb{N}}$ is said to be an *extension* of $\sigma \in \mathbb{N}^{<\mathbb{N}}$ if $\sigma \subseteq \tau$, i.e., if $\mathrm{lh}(\sigma) \leq \mathrm{lh}(\tau) \wedge \forall i\,(i < \mathrm{lh}(\sigma) \rightarrow \sigma(i) = \tau(i))$. Two finite sequences $\tau_1, \tau_2 \in \mathbb{N}^{<\mathbb{N}}$ are said to be *incompatible* if neither is an extension of the other, i.e., if $\exists i\,(i < \min(\mathrm{lh}(\tau_1), \mathrm{lh}(\tau_2)) \wedge \tau_1(i) \neq \tau_2(i))$. A tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ is said to be *perfect* if each element of $T$ has a pair of incompatible extensions in $T$, i.e., if $(\forall \sigma \in T)\,(\exists \tau_1, \tau_2 \in T)\,(\sigma \subseteq \tau_1 \wedge \sigma \subseteq \tau_2 \wedge \tau_1, \tau_2$ are incompatible).

In this section, we shall be mainly concerned with perfect trees $P \subseteq 2^{<\mathbb{N}}$. Such trees may be regarded as codes for perfect closed subsets of $2^{\mathbb{N}}$.

DEFINITION V.4.2. Within $\mathsf{RCA}_0$, let $A$ be an analytic set (given by an analytic code, definitions V.1.5 and V.1.6). We say that $A$ *is countable* if there exists a sequence $\langle X_n\colon n \in \mathbb{N}\rangle$ such that $\forall X\,(X \in A \rightarrow \exists n\,(X = X_n))$. We say that $A$ *contains a nonempty perfect set* if there exists a nonempty perfect tree $P \subseteq 2^{<\mathbb{N}}$ such that $\forall X\,(X$ is a path through $P \rightarrow X \in A)$.

The purpose of this section is to prove within $\mathsf{ATR}_0$ the following theorem, which is known as the *perfect set theorem*.

THEOREM V.4.3 (perfect set theorem in $\mathsf{ATR}_0$). *The following is provable in* $\mathsf{ATR}_0$. *Let $A$ be an analytic code. If $A$ is not countable, then $A$ contains a nonempty perfect set.*

REMARKS V.4.4 (the continuum hypothesis). The perfect set theorem may be regarded as a form of the continuum hypothesis (applied to analytic sets). The paths of a nonempty perfect tree $P \subseteq 2^{<\mathbb{N}}$ are clearly in one-to-one correspondence with the points of $2^{\mathbb{N}}$. Thus the perfect set theorem says that $A$ is either countable or of cardinality $2^{\aleph_0}$.

In §VI.3 we shall study another theorem of classical descriptive set theory which may also be regarded as a form of the continuum hypothesis. This is *Silver's theorem* to the effect that the set of equivalence classes of a coanalytic equivalence relation on $2^{\mathbb{N}}$ is either countable or of cardinality $2^{\aleph_0}$.

The proof of theorem V.4.3 will be based on the following definition and lemma.

DEFINITION V.4.5. Within $\mathsf{ACA}_0$, let $A$ be an analytic code. For any finite sequence $\tau = \langle(\xi_0, m_0), \ldots, (\xi_{k-1}, m_{k-1})\rangle \in A$ we write $\tau' = \langle\xi_0, \ldots, \xi_{k-1}\rangle$. Note that $\tau' \in 2^{<\mathbb{N}}$ and $\mathrm{lh}(\tau') = \mathrm{lh}(\tau)$. Two finite sequences $\tau_1, \tau_2 \in A$ are said to be *strongly incompatible* if $\tau_1'$ and $\tau_2'$ are incompatible. Let $A'$ be the set of all $\sigma \in A$ such that $\sigma$ has a pair of strongly incompatible extensions in $A$. Note that $A'$ is again an analytic code, and $A' \subseteq A$.

LEMMA V.4.6. *The following is provable in* $\mathsf{ATR}_0$. *Let $A$ be an analytic code. For any countable well ordering $X$, there exists a sequence of analytic codes $\langle A_j : j \in \mathrm{field}(X)\rangle$ such that for all $j \in \mathrm{field}(X)$ and $\sigma \in \mathrm{Seq}$,*

$$\sigma \in A_j \leftrightarrow (\sigma \in A \wedge \forall i\,(i <_X j \rightarrow \sigma \in A_i')).$$

PROOF. This is a straightforward instance of arithmetical transfinite recursion. Let $\theta(\sigma, j, Y)$ be the following arithmetical formula: $j \in \mathrm{field}(X) \wedge \sigma \in A \wedge \forall i\,(i <_X j \rightarrow \exists$ strongly incompatible $\tau_1, \tau_2 \supseteq \sigma$ such that $(\tau_1, i), (\tau_2, i) \in Y)$. Given a countable well ordering $X$, let $Y$ be the result of iterating $\theta$ along $X$, i.e., let $Y$ be such that $\mathrm{H}_\theta(X, Y)$ holds. For each $j \in \mathrm{field}(X)$ set $A_j = Y_j = \{\sigma : (\sigma, j) \in Y\}$. Then $\langle A_j : j \in \mathrm{field}(X)\rangle$ has the desired properties. □

REMARK V.4.7. The thought behind lemma V.4.6 is that we wish to define, for each countable ordinal $\alpha$, an analytic code $A_\alpha$, where $A_0 = A$, $A_{\alpha+1} = A_\alpha'$, and $A_\delta = \bigcap_{\alpha<\delta} A_\alpha$ for limit ordinals $\delta$. Lemma V.4.6 says that this definition can be carried out up to any given countable ordinal $\alpha = |X|$. (See also definition V.2.10.)

REMARK V.4.8 (the method of pseudohierarchies). In order to finish the proof of theorem V.4.3, we shall introduce a technique which has not

previously appeared in this book. The new technique is known as *the method of pseudohierarchies*. In the present context, the method of pseudohierarchies takes the form of a generalization of lemma V.4.6 in which the countable well ordering $X$ is replaced by a countable linear ordering which is not a well ordering. The sequence $\langle A_j : j \in \text{field}(X)\rangle$ is then called a pseudohierarchy.

Rather than obtain theorem V.4.3 as an application of an abstract result on the existence of pseudohierarchies, we shall simply present the proof of theorem V.4.3 in the simplest possible way. After that, we shall comment on pseudohierarchies in general (see lemma V.4.12 below).

PROOF OF THEOREM V.4.3. We reason within $\mathsf{ATR}_0$. Let $A$ be a given analytic code. The proof splits into two cases.

Case 1. Assume that there exists a countable well ordering $X$ and a sequence $\langle A_j : j \in \text{field}(X)\rangle$ as in lemma V.4.6 such that in addition $A_j = \emptyset$ for some $j \in \text{field}(X)$. (Here $\emptyset$ denotes the empty set.)

Fix $j$ such that $A_j = \emptyset$. Then for each $\sigma \in A$ there is a unique $i$ such that $i <_X j$ and $\sigma \in A_i$ and $\sigma \notin A'_i$. With this $i$ we define a function $Y_\sigma : \mathbb{N} \to \{0,1\}$ by: $Y_\sigma(n) = 1$ if there exists $\tau \in A_i$ such that $\tau \supseteq \sigma$ and $\text{lh}(\tau) > n$ and $\tau'(n) = 1$; $Y_\sigma(n) = 0$ otherwise. (Here $\tau'$ is as in definition V.4.5.) Thus $\langle Y_\sigma : \sigma \in A\rangle$ is a sequence of points in the Cantor space $2^{\mathbb{N}}$; the sequence exists by arithmetical comprehension. We claim that $\forall Y\,(Y \in A \to \exists \sigma\,(\sigma \in A \wedge Y = Y_\sigma))$. To see this, suppose $Y \in A$. By definition V.1.6 let $f : \mathbb{N} \to \mathbb{N}$ be such that $\forall k\, A(Y[k], f[k])$. Let $i <_X j$ be such that $\forall k\, A_i(Y[k], f[k])$ but $\neg\forall k\, A'_i(Y[k], f[k])$. Let $k$ be such that $\neg A'_i(Y[k], f[k])$. Put $\sigma = \langle (Y(0), f(0)), \ldots, (Y(k-1), f(k-1))\rangle$. Clearly $\sigma \in A_i$, $\sigma \notin A'_i$, and $Y = Y_\sigma$. This proves our claim. Thus $A$ is countable.

Theorem V.4.3 has now been proved under the hypothesis of case 1.

Case 2. Assume that the hypothesis of case 1 does not hold (for the given analytic code $A$).

Let $\varphi(X)$ be the following $\Sigma^1_1$ formula: $\text{LO}(X)$ and there exists a sequence of analytic codes $\langle A_j : j \in \text{field}(X)\rangle$ such that $\forall j\,\forall \sigma\,(\sigma \in A_j \leftrightarrow (j \in \text{field}(X) \wedge \sigma \in A \wedge \forall i\,(i <_X j \to \sigma \in A'_i)))$ and $\forall j\,(j \in \text{field}(X) \to A_j \neq \emptyset)$. By lemma V.4.6 and our assumption, we have $\forall X\,(\text{WO}(X) \to \varphi(X))$. But by theorem V.1.9 we have $\neg\forall X\,(\text{WO}(X) \leftrightarrow \varphi(X))$. Hence $\exists X\,(\varphi(X) \wedge \neg\text{WO}(X))$. In other words, there exists an $X$ and a sequence $\langle A_j : j \in \text{field}(X)\rangle$ such that $X$ is a countable linear ordering and

$$\forall j\,\forall \sigma\,(\sigma \in A_j \leftrightarrow (j \in \text{field}(X) \wedge \sigma \in A \wedge \forall i\,(i <_X j \to \sigma \in A'_i)))$$

and $\forall j\,(j \in \text{field}(X) \to A_j \neq \emptyset)$ and $X$ is not a well ordering.

Fix an $X$ and a sequence $\langle A_j : j \in \text{field}(X)\rangle$ as above. In particular $\forall i\,\forall j\,(i <_X j \to A_j \subseteq A'_i)$. Since $X$ is not a well ordering, let $f : \mathbb{N} \to \text{field}(X)$ be a descending sequence through $X$, i.e., for all $n$, $f(n+1) <_X f(n)$. Hence $A_{f(n)} \subseteq A'_{f(n+1)}$, i.e., each $\sigma \in A_{f(n)}$ has a pair of strongly

incompatible extensions in $A_{f(n+1)}$. Since also $A_{f(0)} \neq \emptyset$, we can define by recursion a function $g\colon 2^{<\mathbb{N}} \to A$ such that for all $\rho \in 2^{<\mathbb{N}}$, $g(\rho) \in A_{f(\mathrm{lh}(\rho))}$ and moreover $g(\rho^\frown\langle 0\rangle)$ and $g(\rho^\frown\langle 1\rangle)$ are strongly incompatible extensions of $g(\rho)$. Let $P$ be the set of all $\sigma \in 2^{<\mathbb{N}}$ such that $\exists\rho\,(\rho \in 2^{<\mathbb{N}} \wedge \sigma \subseteq g(\rho)')$. (The notation $\tau'$ for $\tau \in A$ was defined in V.4.5.) Clearly $P$ is a nonempty perfect subtree of $2^{<\mathbb{N}}$ and $\forall Y\,(Y$ is a path through $P \to Y \in A)$.

This completes the proof of theorem V.4.3.

Let $B$ be a Borel set (given by a Borel code). We say that $B$ *is countable* if there exists a sequence $\langle X_n\colon n \in \mathbb{N}\rangle$ such that $\forall X\,(X \in B \to \exists n\,(X = X_n))$. We say that $B$ *contains a nonempty perfect set* if there exists a nonempty perfect tree $P \subseteq 2^{<\mathbb{N}}$ such that $\forall X\,(X$ is a path through $P \to X \in B)$.

COROLLARY V.4.9. *The following is provable in* $\mathsf{ATR}_0$. *Let $B$ be a Borel code. Either $B$ is countable or $B$ contains a nonempty perfect set.*

PROOF. This is an immediate consequence theorem V.4.3 in view of theorem V.3.8. □

In the next section we shall see that both the perfect set theorem V.4.3 and its corollary, V.4.9 (or even the special case of V.4.9 in which $B$ is a closed subset of $2^{\mathbb{N}}$), are provably equivalent to $\mathsf{ATR}_0$ over the weak base theory $\mathsf{ACA}_0$. Thus $\mathsf{ATR}_0$ is the weakest subsystem of second order arithmetic in which these results can be proved.

A further important result on perfect sets is the Cantor-Bendixson theorem. We shall see in chapter VI that this theorem is not provable in $\mathsf{ATR}_0$ but is provable in the stronger system $\Pi^1_1\text{-}\mathsf{CA}_0$.

EXERCISE V.4.10. Show that the following is provable in $\mathsf{ATR}_0$. Let $A_n$, $n \in \mathbb{N}$, be a sequence of analytic codes. If $\forall n\,(A_n$ is countable), then $\bigcup_{n\in\mathbb{N}} A_n$ (as defined in exercise V.1.12) is countable. Hint: Use theorem V.4.3.

EXERCISE V.4.11. Show that the following is provable in $\mathsf{ATR}_0$. If $A_n$, $n \in \mathbb{N}$, is a sequence of analytic codes, then there exists a sequence of points $X_m$, $m \in \mathbb{N}$, such that $\forall n\,\forall X\,((X \in A_n \wedge A_n$ countable$) \to \exists m\, X = X_m)$.

We end this section with an abstract formulation of the method of pseudohierarchies.

Let $\theta$ be a given arithmetical formula as in definition V.2.4. By a *hierarchy* for $\theta$ we mean a set $Y$ such that $\mathrm{H}_\theta(X, Y)$ holds for some $X$ such that $\mathrm{WO}(X)$. Thus, the principal axiom of $\mathsf{ATR}_0$ asserts the existence of "sufficiently many" hierarchies. By a pseudohierarchy for $\theta$ we mean a set $Y$ such that $\mathrm{H}_\theta(X, Y)$ holds for some $X$ such that $\mathrm{LO}(X) \wedge \neg\mathrm{WO}(X)$. The following lemma asserts the existence of "sufficiently many" pseudohierarchies.

LEMMA V.4.12 (existence of pseudohierarchies). *The following is provable in* $\mathsf{ACA}_0$. *Let* $\theta(n, Y)$ *be an arithmetical formula as in definition* V.2.4. *Let* $\varphi(X, Y)$ *be a* $\Sigma^1_1$ *formula. If*

$$\forall X\,(\mathrm{WO}(X) \to \exists Y\,(\mathrm{H}_\theta(X, Y) \wedge \varphi(X, Y)))$$

*then*

$$\exists X\,\exists Y\,(\mathrm{LO}(X) \wedge \neg\mathrm{WO}(X) \wedge \mathrm{H}_\theta(X, Y) \wedge \varphi(X, Y)).$$

PROOF. Let $\varphi'(X)$ be the following $\Sigma^1_1$ formula:

$$\mathrm{LO}(X) \wedge \exists Y\,(\mathrm{H}_\theta(X, Y) \wedge \varphi(X, Y)).$$

By hypothesis we have $\forall X\,(\mathrm{WO}(X) \to \varphi'(X))$. But by theorem V.1.9 we have $\neg\forall X\,(\mathrm{WO}(X) \leftrightarrow \varphi'(X))$. Hence $\exists X\,(\varphi'(X) \wedge \neg\mathrm{WO}(X))$, Q.E.D. □

These pseudohierarchies provide a powerful and apparently indispensable proof technique within $\mathsf{ATR}_0$. The idea of lemma V.4.12 has already been applied in the proof of theorem V.4.3, case 2, above. Other applications of the same idea are in §§V.7 and V.8.

**Notes for §V.4.** Pseudohierarchies were introduced by Spector [254] and Gandy [88] in the context of hyperarithmetical theory; see §VIII.3 below. Further work on pseudohierarchies is in Harrison [106], Friedman [62, chapters II and III], Steel [256, chapter I], and Friedman/McAloon/Simpson [76].

## V.5. Reversals

In §§V.3 and V.4 we have seen that several theorems of classical descriptive set theory are provable in the formal system $\mathsf{ATR}_0$. We shall now show that each of these theorems is, in a suitable sense, equivalent to $\mathsf{ATR}_0$.

We begin with the reversal of Lusin's separation theorem (theorem V.3.9). We shall essentially show that Lusin's theorem implies arithmetical transfinite recursion. There is a slight conceptual difficulty here since the statement of Lusin's theorem mentions Borel sets. Our concept of Borel set (definitions V.3.1, V.3.2, V.3.4) depends on arithmetical transfinite recursion in order to prove the existence of the needed evaluation maps (lemma V.3.3). Therefore, in the absence of arithmetical transfinite recursion, it is not even clear how to state Lusin's theorem in a meaningful way. In order to circumvent this difficulty, we adopt the following procedure. We first deduce from Lusin's theorem a simple consequence, the so-called $\Sigma^1_1$ separation principle, which does not mention Borel sets. We then show that the $\Sigma^1_1$ separation principle implies arithmetical transfinite recursion.

THEOREM V.5.1 ($\mathsf{ATR}_0$ and $\Sigma^1_1$ separation). *The following are equivalent over* $\mathsf{RCA}_0$:

1. *Arithmetical transfinite recursion.*
2. *The* $\Sigma^1_1$ separation principle: *For any* $\Sigma^1_1$ *formulas* $\varphi_1(n)$ *and* $\varphi_0(n)$ *in which* $Z$ *does not occur freely, we have*

$$\neg\exists n\,(\varphi_1(n) \wedge \varphi_0(n)) \to \exists Z\,\forall n\,((\varphi_1(n) \to n \in Z) \wedge (\varphi_0(n) \to n \notin Z)).$$

*Here* $Z$ *ranges over subsets of* $\mathbb{N}$.

PROOF. We first show how to prove the $\Sigma^1_1$ separation principle in $\mathsf{ATR}_0$, via Lusin's theorem. Reasoning within $\mathsf{ATR}_0$, assume $\neg\exists n\,(\varphi_1(n)\wedge\varphi_0(n))$. Let $\langle X_n : n \in \mathbb{N}\rangle$ be a fixed sequence of distinct points in the Cantor space $2^{\mathbb{N}}$. (E.g., we may take $X_n(m) = 1$ if $m < n$, 0 otherwise.) By theorem V.1.7 there exist analytic codes $A_i$, $i < 2$, such that $\forall X\,(X \in A_i \leftrightarrow \exists n\,(X = X_n \wedge \varphi_i(n)))$. By Lusin's theorem in $\mathsf{ATR}_0$ (theorem V.3.9), let $B$ be a Borel code such that $\forall X\,((X \in A_1 \to X \in B)\wedge(X \in A_0 \to X \notin B))$. By lemma V.3.7 let $Z \subseteq \mathbb{N}$ be such that $\forall n\,(n \in Z \leftrightarrow X_n \in B)$. Then $\varphi_1(n)$ implies $X_n \in A_1$ which implies $X_n \in B$, i.e., $n \in Z$, and similarly $\varphi_0(n)$ implies $n \notin Z$. This proves the implication $1 \to 2$.

For the converse implication, assume the $\Sigma^1_1$ separation principle. In particular we have arithmetical (in fact $\Delta^1_1$) comprehension. Let $X$ be a given countable well ordering and let $\theta(n, Y)$ be a given arithmetical formula. We wish to prove the existence of a $Z$ such that $\mathrm{H}_\theta(X, Z)$ holds (cf. definition V.2.4). Define $\Sigma^1_1$ formulas

$$\varphi_1(j, n) \equiv \exists Y\,(\mathrm{H}_\theta(j, X, Y) \wedge \theta(n, j, Y))$$

and

$$\varphi_0(j, n) \equiv \exists Y\,(\mathrm{H}_\theta(j, X, Y) \wedge \neg\theta(n, j, Y)).$$

Then by lemma V.2.3 we have $\neg\exists j\,\exists n\,(\varphi_1(j, n) \wedge \varphi_0(j, n))$. Hence by $\Sigma^1_1$ separation there exists $W \subseteq \mathbb{N}$ such that $\forall j\,\forall n\,((\varphi_1(j, n) \to (n, j) \in W) \wedge (\varphi_0(j, n) \to (n, j) \notin W))$. For each $j$ put

$$W^j = \{(m, i) : i <_X j \wedge (m, i) \in W\}.$$

We claim that $\mathrm{H}_\theta(j, X, W^j)$ and $\forall n\,((n, j) \in W \leftrightarrow \theta(n, j, W^j))$ hold for all $j \in \mathrm{field}(X)$. Assume inductively that the claim holds for all $i <_X j$. By definition V.2.2 it follows that $\mathrm{H}_\theta(j, X, W^j)$ holds. By lemma V.2.3 we have $\forall n\,((\varphi_1(j, n) \leftrightarrow \theta(n, j, W^j)) \wedge (\varphi_0(j, n) \leftrightarrow \neg\theta(n, j, W^j)))$. Hence by the choice of $W$ we have $\forall n\,((n, j) \in W \leftrightarrow \theta(n, j, W^j))$. Our claim now follows by arithmetical transfinite induction (lemma V.2.1) along $X$.

From the claim and definition V.2.2 it follows that $\mathrm{H}_\theta(X, Z)$ holds if we define $Z = \{(n, j) : (n, j) \in W \wedge j \in \mathrm{field}(X)\}$. This completes the proof. □

We now turn to the reversal of theorem V.3.11. Theorem V.3.11 says that the domain of a single-valued Borel relation is Borel. As in the case of Lusin's theorem, our procedure for the the reversal will be to formulate a consequence of theorem V.3.11 which does not mention Borel sets, and then to prove $\mathsf{ATR}_0$ from this consequence.

THEOREM V.5.2 ($\mathsf{ATR}_0$ and unique paths). *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Arithmetical transfinite recursion*.
2. *The scheme*

$$\forall i\,(\exists \text{ at most one } X)\,\varphi(i,X) \to \exists Z\,\forall i\,(i \in Z \leftrightarrow \exists X\,\varphi(i,X)),$$

*where* $\varphi(i,X)$ *is any arithmetical formula in which* $Z$ *does not occur.*
3. *For any sequence of trees* $\langle T_i : i \in \mathbb{N}\rangle$, *if* $\forall i\,(T_i$ *has at most one path*) *then* $\exists Z\,\forall i\,(i \in Z \leftrightarrow T_i$ *has a path*).

PROOF. We first show how to prove 2 within $\mathsf{ATR}_0$, via theorem V.3.11. Assume $\forall i\,(\exists \text{ at most one } Y)\,\varphi(i,Y)$ where $\varphi$ is arithmetical. Let $\langle X_i : i \in \mathbb{N}\rangle$ be any fixed sequence of distinct points in $2^{\mathbb{N}}$. By theorems V.1.7 and V.3.10 let $C$ be a Borel code such that $\forall X\,\forall Y\,(C(X,Y) \leftrightarrow \exists i\,(X = X_i \wedge \varphi(i,Y)))$. Then $\forall X\,(\exists \text{ at most one } Y)\,C(X,Y)$ so by theorem V.3.11 let $B$ be a Borel code such that $\forall X\,(X \in B \leftrightarrow \exists Y\,C(X,Y))$. By lemma V.3.7 let $Z \subseteq \mathbb{N}$ be such that $\forall i\,(i \in Z \leftrightarrow X_i \in B)$. Then clearly $\forall i\,(i \in Z \leftrightarrow \exists Y \varphi(i,Y))$. This proves the implication $1 \to 2$.

Next we prove the converse, $2 \to 1$. Assume 2. In particular we have arithmetical comprehension. We wish to prove arithmetical transfinite recursion. Let $X$ be a given countable well ordering, and let $\theta(n,j,Y)$ be a given arithmetical formula. Let $\varphi(i,Y)$ be the following arithmetical formula: $\exists n\,\exists j\,(i = (n,j) \wedge \mathrm{H}_\theta(j,X,Y) \wedge \theta(n,j,Y))$. By lemma V.2.3 we have $\forall i\,(\exists \text{ at most one } Y)\,\varphi(i,Y)$. Hence by 2 let $Z \subseteq \mathbb{N}$ be such that $\forall i\,(i \in Z \leftrightarrow \exists Y\,\varphi(i,Y))$. For each $k$ set $Z^k = \{(n,j) : j <_X k \wedge (n,j) \in Z\}$. By arithmetical transfinite induction along $X$ (lemma V.2.1) we see that $\mathrm{H}_\theta(j,X,Z^j)$ and $\forall n\,((n,j) \in Z \leftrightarrow \theta(n,j,Z^j))$ for all $j \in \mathrm{field}(X)$. From this it follows easily that $\mathrm{H}_\theta(X,Z)$ holds. Thus we have arithmetical transfinite recursion.

It remains to prove that V.5.2.2 is equivalent to V.5.2.3. The statement V.5.2.3 is the special case of V.5.2.2 with $\varphi(i,X) \equiv (X$ encodes a path through $T_i)$. So the implication from V.5.2.2 to V.5.2.3 is trivial. For the converse, we prove two lemmas.

LEMMA V.5.3. *It is provable in* $\mathsf{RCA}_0$ *that* V.5.2.3 *implies arithmetical comprehension*.

PROOF. Assume V.5.2.3. Instead of arithmetical comprehension we shall prove the equivalent statement III.1.3.3. Let $f : \mathbb{N} \to \mathbb{N}$ be given. Define a sequence of trees $\langle T_i : i \in \mathbb{N}\rangle$ by putting $\tau \in T_i$ if and only if $\forall m\,(m < \mathrm{lh}(\tau) \to (\tau(m) = 0 \wedge f(m) \neq i))$. Clearly $\forall i\,(T_i$ has at most

one path) and $\forall i\,(T_i$ has a path $\leftrightarrow \forall m\,(f(m) \neq i))$. So by the assumption V.5.2.3 there exists $Z$ such that $\forall i\,(i \in Z \leftrightarrow \forall m\,(f(m) \neq i))$. Hence by lemma III.1.3 we have arithmetical comprehension. □

The next lemma is an improvement of lemma V.1.4, our formal version of the Kleene normal form theorem.

LEMMA V.5.4. *For any arithmetical formula $\varphi(X)$ we can find an arithmetical (in fact $\Sigma^0_0$) formula $\theta(\sigma,\tau)$ such that* $\mathsf{ACA}_0$ *proves*

$$\forall X\,(\varphi(X) \leftrightarrow \exists f\,\forall m\,\theta(X[m], f[m]))$$

*and*

$$\forall X\,(\exists \text{ at most one } f)\,\forall m\,\theta(X[m], f[m])).$$

(Here $X$ ranges over subsets of $\mathbb{N}$ and $f$ ranges over total functions from $\mathbb{N}$ into $\mathbb{N}$. Also $X[m] = \langle \xi_0, \xi_1, \ldots, \xi_{m-1}\rangle$ where $\xi_i = 1$ if $i \in X$, 0 if $i \notin X$. Note that $\varphi(X)$ may contain free variables other than $X$. If this is the case, then $\theta(\sigma,\tau)$ will also contain those free variables.)

PROOF. Replacing $\forall n$ by $\neg\exists n\,\neg$, we may safely assume that the given arithmetical formula $\varphi$ contains no universal quantifiers. Let $\langle \exists n\,\psi_i : i < k\rangle$ be a list of all subformulas of $\varphi$ of the form $\exists n\,\psi$ where $n$ is any number variable. For each $i < k$ let $m_{i1}, \ldots, m_{ik_i}$ be a list of the free number variables occurring in $\exists n\,\psi_i$. Functions $g_i : \mathbb{N}^{k_i} \to \mathbb{N}$, $i < k$ are called *minimal Skolem functions* if for all $i < k$ and all $m_{i1}, \ldots, m_{ik_i} \in \mathbb{N}$,

$$g_i(m_{i1}, \ldots, m_{ik_i}) = \begin{cases} 0 & \text{if } \neg\exists n\,\psi_i(m_{i1}, \ldots, m_{ik_i}, n), \\ n_i + 1 & \text{if } n_i = \text{least } n \text{ such that } \psi_i(m_{i1}, \ldots, m_{ik_i}, n). \end{cases}$$

By arithmetical comprehension there is for any given $X$ a unique set of minimal Skolem functions. Given any functions $g_i : \mathbb{N}^{k_i} \to \mathbb{N}$, $i < k$, we associate to each subformula $\psi$ of $\varphi$ a formula $\overline{\psi}$ in terms of the given $g_i$, $i < k$, as follows: $\psi \equiv \overline{\psi}$ if $\psi$ is atomic, $\overline{\psi_1 \wedge \psi_2} \equiv \overline{\psi_1} \wedge \overline{\psi_2}$, $\overline{\neg\psi} \equiv \neg\overline{\psi}$, and $\overline{\exists n\,\psi_i} \equiv (g_i(m_{i1}, \ldots, m_{ik_i}) > 0)$. Thus, for any given $X$, we see that $\varphi(X)$ holds if and only if there exist functions $g_i : \mathbb{N}^{k_i} \to \mathbb{N}$, $i < k$, such that $\overline{\varphi}$ holds and, for all $i < k$ and all $m_{i1}, \ldots, m_{ik_i}, n_i, n \in \mathbb{N}$,

$$\begin{cases} g_i(m_{i1}, \ldots, m_{ik_i}) = 0 \to \neg\overline{\psi_i}(m_{i1}, \ldots, m_{ik_i}, n), \\ g_i(m_{i1}, \ldots, m_{ik_i}) = n_i + 1 \to \overline{\psi_i}(m_{i1}, \ldots, m_{ik_i}, n_i), \quad \text{and} \\ (g_i(m_{i1}, \ldots, m_{ik_i}) = n_i + 1 \wedge n < n_i) \to \neg\overline{\psi_i}(m_{i1}, \ldots, m_{ik_i}, n). \end{cases} \tag{$*$}$$

Furthermore, for a given $X$, these functions $g_i$, $i < k$, are unique if they exist. Now let $\forall m\,\theta(X[m], f[m])$ say that $f(n) = 0$ for all $n$ not of the form $\langle i, m_{i1}, \ldots, m_{ik_i}\rangle$, $i < k$, and furthermore that $\overline{\varphi}$ and $(*)$ hold when the $g_i$, $i < k$ are defined by $g_i(m_{i1}, \ldots, m_{ik_i}) = f(\langle i, m_{i1}, \ldots, m_{ik_i}\rangle)$. Clearly this $\theta$ has the desired properties. Lemma V.5.4 is proved. □

We are now ready to finish the proof of theorem V.5.2. Assume V.5.2.3. Hence by lemma V.5.3 we have arithmetical comprehension. We wish to

prove V.5.2.2. Assume $\forall i\,(\exists \text{ at most one } X)\,\varphi(i, X)$ where $\varphi$ is arithmetical. By lemma V.5.4 there is an arithmetical formula $\theta$ such that

$$\forall i\,(\forall X\,\varphi(i, X) \leftrightarrow \exists f\,\forall k\,\theta(i, X[k], f[k]))$$

and $\forall i\,(\exists$ at most one pair $(X, f)$ such that $\forall k\,\theta(i, X[k], f[k]))$. Define a sequence of trees $\langle T_i : i \in \mathbb{N}\rangle$ by putting $\tau \in T_i$ if and only if $\tau$ is of the form $\langle(\xi_0, n_0), \ldots, (\xi_{k-1}, n_{k-1})\rangle$ and $\forall j < k\,(\xi_j \in \{0, 1\} \wedge n_j \in \mathbb{N})$ and $\forall j \leq k\,(\theta(i, \langle\xi_0, \ldots, \xi_{j-1}\rangle, \langle n_0, \ldots, n_{j-1}\rangle)$. ($T_i$ is in fact an analytic code. Compare the proof of theorem V.1.7′.) Clearly $\forall i\,(T_i$ has at most one path) and $\forall i\,(T_i$ has a path $\leftrightarrow \exists X\,\varphi(i, X))$. By the assumption V.5.2.3 there exists $Z \subseteq \mathbb{N}$ such that $\forall i\,(i \in Z \leftrightarrow T_i$ has a path). Hence $\forall i\,(i \in Z \leftrightarrow \exists X\,\varphi(i, X))$. This completes the proof of theorem V.5.2. □

We now turn to the reversal of the perfect set theorem V.4.3 and of its corollary, V.4.9.

THEOREM V.5.5 ($\mathsf{ATR}_0$ and the perfect set theorem). *The following are pairwise equivalent over* $\mathsf{ACA}_0$.

1. *Arithmetical transfinite recursion*.
2. *The* perfect set theorem: *For every analytic code A, if A is uncountable, then A has a nonempty perfect subset*.
3. *For every tree* $T \subseteq 2^{<\mathbb{N}}$, *if T has uncountably many paths, then T has a nonempty perfect subtree.*
4. *For every tree* $T \subseteq \mathbb{N}^{<\mathbb{N}}$, *if T has uncountably many paths, then T has a nonempty perfect subtree.*

(A tree $T$ is said to have *uncountably many paths* if for all sequences of functions $\langle f_n : n \in \mathbb{N}\rangle$ there exists a function $f$ such that $f$ is a path through $T$ and $\forall n\,(f \neq f_n)$.)

PROOF. That 1 implies 2 has already been proved as theorem V.4.3. To show that 2 implies 3, let $T$ be a given subtree of $2^{<\mathbb{N}}$. Let $A$ be the set of all finite sequences of the form $\langle(\xi_0, 0), \ldots, (\xi_{k-1}, 0)\rangle$ such that $\langle\xi_0, \ldots, \xi_{k-1}\rangle \in T$. Then $A$ is an analytic code. Thus 2 contains 3 as a special case.

The proof that 3 implies 4 will be based on a canonical homeomorphism of the Baire space $\mathbb{N}^{\mathbb{N}}$ into the Cantor space $2^{\mathbb{N}}$. Given $f : \mathbb{N} \to \mathbb{N}$, define $f^* : \mathbb{N} \to \{0, 1\}$ by

$$f^*(n) = \begin{cases} 1 & \text{if } \exists k\,(n = k + \sum_{i=0}^{k} f(i)), \\ 0 & \text{otherwise.} \end{cases}$$

LEMMA V.5.6. *The following is provable in* $\mathsf{RCA}_0$. *For any tree* $T \subseteq \mathbb{N}^{<\mathbb{N}}$ *there exists a tree* $T^* \subseteq 2^{<\mathbb{N}}$ *such that* $\forall f\,(f$ *is a path through* $T \leftrightarrow f^*$ *is a path through* $T^*)$.

PROOF. Let $T^*$ be the set of all $\tau \in 2^{<\mathbb{N}}$ of the form

$$\underbrace{\langle 0,\dots,0\rangle}_{m_0}{}^\frown\langle 1\rangle{}^\frown\underbrace{\langle 0,\dots,0\rangle}_{m_1}{}^\frown\langle 1\rangle{}^\frown\cdots{}^\frown\underbrace{\langle 0,\dots,0\rangle}_{m_{k-1}}{}^\frown\langle 1\rangle{}^\frown\underbrace{\langle 0,\dots,0\rangle}_{n}$$

where $\langle m_0, m_1, \dots, m_{k-1}\rangle \in T$ and $n \in \mathbb{N}$. Clearly $T^*$ has the desired property. □

In particular, if $T$ has uncountably many paths, then so does $T^*$. On the other hand, if $T^*$ has a nonempty perfect subtree $P$, then by recursion we can define a nonempty perfect subtree $Q \subseteq P$ such that any path $g$ through $Q$ has $g(n) = 1$ for infinitely many $n$; hence $g = f^*$ for some $f : \mathbb{N} \to \mathbb{N}$. Let $R$ be the set of all $\langle m_0, \dots, m_{k-1}\rangle \in \mathbb{N}^{<\mathbb{N}}$ such that

$$\underbrace{\langle 0,\dots,0\rangle}_{m_0}{}^\frown\langle 1\rangle{}^\frown\underbrace{\langle 0,\dots,0\rangle}_{m_1}{}^\frown\langle 1\rangle{}^\frown\cdots{}^\frown\underbrace{\langle 0,\dots,0\rangle}_{m_{k-1}}{}^\frown\langle 1\rangle$$

belongs to $Q$. Then clearly $R$ is a nonempty perfect subtree of $T$. In sum, V.5.5.4 for $T$ follows from V.5.5.3 applied to $T^*$.

It remains to prove that V.5.5.4 implies arithmetical transfinite recursion. Instead of proving arithmetical transfinite recursion directly, we shall prove the equivalent statement V.5.2.3. Let $\langle T_i : i \in \mathbb{N}\rangle$ be a given sequence of trees such that $\forall i\,(T_i$ has at most one path). Form a tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ by

$$T = \{\langle\rangle\} \cup \{\langle i\rangle{}^\frown\tau : i \in \mathbb{N} \wedge \tau \in T_i\}.$$

Clearly $T$ has no nonempty perfect subtree. Therefore, by V.5.5.4, $T$ has only countably many paths, i.e., there exists a sequence $\langle f_n : n \in \mathbb{N}\rangle$ such that $\forall f\,(f$ is a path through $T \to \exists n\,(f = f_n))$. By arithmetical comprehension let $Z$ be the set of all $i \in \mathbb{N}$ such that $\exists n\,(f_n(0) = i \wedge f_n$ is a path through $T)$. Then clearly $\forall i\,(i \in Z \leftrightarrow T_i$ has a path). Hence by theorem V.5.2 we have arithmetical transfinite recursion.

This completes the proof of theorem V.5.5. □

The results of this section, especially theorem V.5.1, will be applied in later sections to show that other theorems of ordinary mathematics are equivalent to $\mathsf{ATR}_0$.

EXERCISE V.5.7. Show that $\Sigma^1_1$-$\mathsf{AC}_0$ proves $\Pi^1_1$ *separation*: For any $\Pi^1_1$ formulas $\psi_1(n)$ and $\psi_0(n)$ in which $Z$ does not occur freely, $\neg\exists n\,(\psi_1(n) \wedge \psi_0(n)) \to \exists Z\,\forall n\,((\psi_1(n) \to n \in Z) \wedge (\psi_0(n) \to n \notin Z))$. This is in contrast to theorem V.5.1.

REMARK V.5.8 (Cantor space versus Baire space). In our treatment of classical descriptive set theory in §V.1 and §§V.3–V.5, we have chosen to work with the Cantor space $2^{\mathbb{N}}$. Since it is customary to work with the Baire space $\mathbb{N}^{\mathbb{N}}$, we are obliged to explain our choice. We adduce the following considerations. (1) There is no real loss of generality, since

the Baire space, or any uncountable complete separable metric space, is Borel-isomorphic to $2^{\mathbb{N}}$. (2) In this book, the second order variables of the language of $Z_2$ range over points of the Cantor space (i.e., subsets of $\mathbb{N}$) rather than points of the Baire space (i.e., functions from $\mathbb{N}$ to $\mathbb{N}$). It is therefore natural for us here to work with $2^{\mathbb{N}}$ rather than $\mathbb{N}^{\mathbb{N}}$. (3) Results concerning $2^{\mathbb{N}}$ are easily compared to chapter IV, which is also concerned with closed subsets of $2^{\mathbb{N}}$ (coded by trees $T \subseteq 2^{<\mathbb{N}}$). The same would not hold for $\mathbb{N}^{\mathbb{N}}$. (4) Our results concerning closed subsets of Cantor space are sometimes sharper than the corresponding results for Baire space. Consider for instance the reversal of the perfect set theorem for closed subsets of $2^{\mathbb{N}}$, i.e., the implication $3 \to 1$ in theorem V.5.5. The corresponding result for $\mathbb{N}^{\mathbb{N}}$ follows trivially from this, but the converse requires a further trick, lemma V.5.6. Thus the reversal of the perfect set theorem for Cantor space is more definitive than the corresponding result for Baire space. A similar remark will also apply to the reversal of the Cantor/Bendixson theorem, in §VI.1.

**Notes for §V.5.** The equivalence $1 \leftrightarrow 4$ of theorem V.5.5 has been announced by Friedman [68, 69]. Theorem V.5.1 has been announced by Simpson [243]. The other results of this section are due to Simpson (previously unpublished).

## V.6. Comparability of Countable Well Orderings

In this section we complete the discussion of countable well orderings which was begun in §V.2 (definitions V.2.7 and V.2.10, lemmas V.2.8 and V.2.9). We show that the set existence axioms of $\mathsf{ATR}_0$ are indispensable for a decent theory of countable ordinals. Clearly a minimum requirement for a decent theory of countable ordinals is that any two countable well orderings are comparable (definition V.2.7). We show that this assertion is equivalent to arithmetical transfinite recursion.

Let CWO be the assertion that any two countable well orderings are comparable, i.e.,

$$\forall X \, \forall Y \, ((\mathrm{WO}(X) \wedge \mathrm{WO}(Y)) \to (|X| \leq |Y| \vee |Y| \leq |X|)).$$

We begin by proving:

Lemma V.6.1. *Over* $\mathsf{RCA}_0$, CWO *implies arithmetical comprehension*.

Proof. Reason in $\mathsf{RCA}_0$ and assume CWO. Instead of proving arithmetical comprehension directly, we shall prove the equivalent assertion III.1.3.3. Let a one-to-one function $f : \mathbb{N} \to \mathbb{N}$ be given. By $\Delta^0_1$ comprehension let $X = \{(m,n) : f(m) \leq f(n)\}$. Clearly $\mathrm{LO}(X)$, and by bounded $\Sigma^0_1$ comprehension each initial section of $X$ is finite; hence $\mathrm{WO}(X)$. Comparing $X$ with the standard well ordering of $\mathbb{N}$, we get

a bijection $g : \mathbb{N} \to \mathbb{N}$ such that $\forall m \forall n (m \leq n \leftrightarrow g(m) \leq_X g(n))$, i.e., $\forall m \forall n (m \leq n \leftrightarrow f(g(m)) \leq f(g(n)))$. Hence for all $k$ we have

$$\exists m (f(m) = k) \leftrightarrow \exists m (m \leq k \wedge f(g(m)) = k).$$

Hence by $\Delta^0_1$ comprehension $\exists Y \forall k (k \in Y \leftrightarrow \exists m (f(m) = k))$, i.e., $\mathrm{rng}(f)$ exists. By lemma III.1.3 this gives arithmetical comprehension. □

An important consequence of CWO is the so-called $\Sigma^1_1$ *bounding principle*:

LEMMA V.6.2 ($\Sigma^1_1$ bounding principle). *The following is provable in* $\mathsf{RCA}_0$. *Assume* CWO. *Then for any* $\Sigma^1_1$ *formula* $\varphi(X)$ *we have*

$$\forall X (\varphi(X) \to \mathrm{WO}(X)) \to \exists Y (\mathrm{WO}(Y) \wedge \forall X (\varphi(X) \to |X| < |Y|)).$$

PROOF. Assume CWO. By lemma V.6.1 we have arithmetical comprehension. Assume the hypothesis $\forall X (\varphi(X) \to \mathrm{WO}(X))$. If the conclusion fails, then by CWO we have $\forall Y (\mathrm{WO}(Y) \to \exists X (\varphi(X) \wedge |X| \geq |Y|))$. Hence $\forall Y (\mathrm{WO}(Y) \leftrightarrow \varphi'(Y))$ where $\varphi'(Y)$ is the following $\Sigma^1_1$ formula: $\mathrm{LO}(Y) \wedge \exists X (\varphi(X) \wedge |X| \geq |Y|)$. This contradicts theorem V.1.9. □

LEMMA V.6.3. *The following is provable in* $\mathsf{RCA}_0$. *Assume* CWO. *If* $\mathrm{WO}(X)$ *and* $\mathrm{WO}(Y)$ *and* $X$ *is isomorphic to a subordering of* $Y$, *then* $|X| \leq |Y|$.

PROOF. If not, then by CWO we would have $|Y| < |X|$, hence $Y$ would be isomorphic to a subordering of an initial section of $Y$. Thus there would be $f : \mathrm{field}(Y) \to \mathrm{field}(Y)$ and $k \in \mathrm{field}(Y)$ such that $\forall m \forall n (m \leq_Y n \leftrightarrow f(m) \leq_Y f(n) <_Y k)$. By arithmetical transfinite induction along $Y$ (lemmas V.6.1 and V.2.1) it is straightforward to prove that $m \leq_Y f(m)$ for all $m \in \mathrm{field}(Y)$. In particular $k \leq_Y f(k)$, a contradiction. □

The key to the proof that CWO implies arithmetical transfinite recursion is the next definition.

DEFINITION V.6.4 (double descent tree). The following definition is made in $\mathsf{RCA}_0$. If $X$ and $Y$ are countable linear orderings, the *double descent tree* $\mathrm{T}(X, Y)$ is the set of all finite sequences of the form

$$\langle (m_0, n_0), (m_1, n_1), \ldots, (m_{k-1}, n_{k-1}) \rangle$$

such that

$$m_0 >_X m_1 >_X \cdots >_X m_{k-1}$$

and

$$n_0 >_Y n_1 >_Y \cdots >_Y n_{k-1}.$$

We write $X * Y = \mathrm{KB}(\mathrm{T}(X, Y)) =$ the Kleene/Brouwer ordering of $\mathrm{T}(X, Y)$.

LEMMA V.6.5. *The following is provable in* $\mathsf{RCA}_0$. *Assume* CWO.

(i) *If* $\mathrm{WO}(X) \wedge \mathrm{LO}(Y)$ *then* $\mathrm{WO}(X * Y)$.

(ii) *If* $\mathrm{WO}(X) \wedge \mathrm{LO}(Y) \wedge \neg\mathrm{WO}(Y)$ *then* $|X| \leq |X * Y|$.

PROOF. Assume CWO. By lemma V.6.1 we have arithmetical comprehension. If $\neg\mathrm{WO}(X * Y)$ then by lemma V.1.3 there is a path through $\mathrm{T}(X, Y)$. Let $\langle (m_i, n_i) : i \in \mathbb{N}\rangle$ be such a path. Then $\langle m_i : i \in \mathbb{N}\rangle$ is a descending sequence through $X$. This proves part (i).

For part (ii), assume that $\mathrm{WO}(X) \wedge \mathrm{LO}(Y) \wedge \neg\mathrm{WO}(Y)$. Let $\mathrm{T}(X)$ be the *descent tree* of $X$, i.e., $\mathrm{T}(X)$ is the set of all finite descending sequences $\langle m_0, m_1, \ldots, m_{k-1}\rangle$, $m_0 >_X m_1 >_X \cdots >_X m_{k-1}$. For each $m \in \mathrm{field}(X)$ let $\sigma_m$ be the KB-least $\sigma \in \mathrm{T}(X)$ such that $\sigma(\mathrm{lh}(\sigma) - 1) = m$. Then $m <_X n$ implies $\sigma_m \leq_{\mathrm{KB}} \sigma_n{}^\frown\langle m\rangle <_{\mathrm{KB}} \sigma_n$. Thus $\langle \sigma_m : m \in \mathrm{field}(X)\rangle$ is an isomorphism of $X$ onto a suborder of $\mathrm{KB}(\mathrm{T}(X))$. Hence by lemmas V.1.3 and V.6.3 we have $|X| \leq |\mathrm{KB}(\mathrm{T}(X))|$. Now let $\langle n_i : i \in \mathbb{N}\rangle$ be a fixed descending sequence through $Y$. Define $f : \mathrm{T}(X) \to \mathrm{T}(X, Y)$ by

$$f(\langle m_0, m_1, \ldots, m_{k-1}\rangle) = \langle (m_0, n_0), (m_1, n_1), \ldots, (m_{k-1}, n_{k-1})\rangle.$$

Clearly $\sigma <_{\mathrm{KB}(\mathrm{T}(X))} \tau$ implies $f(\sigma) <_{\mathrm{KB}} f(\tau)$, so $f$ is an isomorphism of $\mathrm{KB}(\mathrm{T}(X))$ onto a suborder of $\mathrm{KB}(\mathrm{T}(X, Y))$. Hence by part (i) and lemma V.6.3 we have

$$|X| \leq |\mathrm{KB}(\mathrm{T}(X))| \leq |\mathrm{KB}(\mathrm{T}(X, Y))| = |X * Y|.$$

This completes the proof. □

DEFINITION V.6.6 (sum of two linear orderings). Within $\mathsf{RCA}_0$, if $\mathrm{LO}(X)$ and $\mathrm{LO}(Y)$, we define

$$X + Y = \{(2m, 2n) : (m, n) \in X\} \cup \{(2m + 1, 2n + 1) : (m, n) \in Y\}$$
$$\cup \{(2m, 2n + 1) : (m, m) \in X \wedge (n, n) \in Y\}.$$

Clearly $\mathrm{LO}(X + Y)$ and $|X| \leq |X + Y|$. Intuitively $X + Y$ consists of $X$ followed by $Y$. Also $\mathrm{WO}(X + Y)$ if and only if $\mathrm{WO}(X) \wedge \mathrm{WO}(Y)$.

DEFINITION V.6.7 (sum of a sequence of linear orderings). In $\mathsf{RCA}_0$, if $\langle X_i : i \in \mathbb{N}\rangle$ is a sequence of countable linear orderings, we define

$$\sum_{i\in\mathbb{N}} X_i = \{((m, i), (n, i)) : (m, n) \in X_i\}$$
$$\cup \{((m, i), (n, j)) : (m, m) \in X_i \wedge (n, n) \in X_j \wedge i < j\}.$$

Clearly $\mathrm{LO}(\sum_{i\in\mathbb{N}} X_i)$. Intuitively $\sum_{i\in\mathbb{N}} X_i$ is the countable linear ordering $X_0 + X_1 + \cdots + X_i + \cdots$. Also $\mathrm{WO}(\sum_{i\in\mathbb{N}} X_i)$ if and only if $\forall i\ \mathrm{WO}(X_i)$.

If $\mathrm{LO}(X)$ we write

$$X \cdot \mathbb{N} = \sum_{i\in\mathbb{N}} X = X + X + \cdots + X + \cdots.$$

We are now ready to prove the main theorem of this section:

THEOREM V.6.8 ($\mathsf{ATR}_0$ and CWO). *The following are equivalent over* $\mathsf{RCA}_0$.

1. *Arithmetical transfinite recursion*.
2. CWO, *i.e., comparability of countable well orderings, i.e., the statement*

$$\forall X \forall Y ((\mathrm{WO}(X) \wedge \mathrm{WO}(Y)) \to (|X| \leq |Y| \vee |Y| \leq |X|)).$$

PROOF. That $\mathsf{ATR}_0$ implies CWO has already been proved as lemma V.2.9. For the converse, assume CWO. By lemma V.6.1 we have arithmetical comprehension. We wish to prove arithmetical transfinite recursion.

Instead of proving arithmetical transfinite recursion directly, we shall prove the $\Sigma^1_1$ separation principle V.5.1.2. Assume that $\neg\exists n\,(\varphi_1(n) \wedge \varphi_0(n))$ where $\varphi_1(n)$ and $\varphi_0(n)$ are $\Sigma^1_1$. By theorem 1.7′ and lemma V.1.3 there exist sequences of countable linear orderings $\langle X_n : n \in \mathbb{N}\rangle$ and $\langle Y_n : n \in \mathbb{N}\rangle$ such that $\forall n\,(\varphi_1(n) \leftrightarrow \neg\mathrm{WO}(X_n))$ and $\forall n\,(\varphi_0(n) \leftrightarrow \neg\mathrm{WO}(Y_n))$. Our assumption $\neg\exists n\,(\varphi_1(n) \wedge \varphi_0(n))$ implies that

$$\forall n\,(\mathrm{WO}(X_n) \vee \mathrm{WO}(Y_n)).$$

By lemma V.6.5(i) and the $\Sigma^1_1$ bounding principle V.6.2, there exists a countable well ordering $U$ such that

$$\forall X \forall n\,(\mathrm{LO}(X) \wedge \neg\mathrm{WO}(X)) \to |X * Y_n| < |U|).$$

Put $Z_n = (U + X_n) * Y_n$. The choice of $U$ and lemma V.6.5(ii) imply that

$$\forall n\,((\neg\mathrm{WO}(X_n) \to |Z_n| < |U|) \wedge (\neg\mathrm{WO}(Y_n) \to |U| \leq |Z_n|)).$$

By lemmas V.6.5(i) and V.6.2 there exists a countable well ordering $V$ such that $|U| < |V|$ and $\forall n\,(|Z_n| < |V|)$. By arithmetical comprehension we may safely assume that $U$ is an initial section of $V$. Note that $|Z_n + V \cdot \mathbb{N}| = |V + V \cdot \mathbb{N}|$ for all $n$. Put

$$Z = \sum_{n\in\mathbb{N}} (Z_n + V \cdot \mathbb{N})$$

and

$$W = (V + V \cdot \mathbb{N}) \cdot \mathbb{N} = \sum_{n\in\mathbb{N}} (V + V \cdot N).$$

By CWO and lemma V.6.3 there exists an isomorphism $f$ of $Z$ onto $W$. For each $n \in \mathbb{N}$ let $f_n$ be the induced isomorphism of $Z_n + V \cdot \mathbb{N}$ onto $V + V \cdot \mathbb{N}$. Thus $|Z_n| < |U|$ if and only if the image of $Z_n$ under $f_n$ is an initial section of $U$. Hence by arithmetical comprehension, there exists $S \subseteq \mathbb{N}$ such that

$$\forall n\,(n \in S \leftrightarrow |Z_n| < |U|).$$

In particular $\forall n\,((\varphi_1(n) \to n \in S) \wedge (\varphi_0(n) \to n \notin S))$. Thus we have $\Sigma^1_1$ separation. By theorem V.5.1 we have arithmetical transfinite recursion. This completes the proof of theorem V.6.8. □

We can also show that $\mathsf{ATR}_0$ is equivalent to the $\Sigma^1_1$ bounding principle:

THEOREM V.6.9 ($\mathsf{ATR}_0$ and $\Sigma^1_1$ bounding). *The following are equivalent over* $\mathsf{RCA}_0$.

1. *Arithmetical transfinite recursion*.
2. *For any analytic code* $A$, *if* $\forall X\,(X \in A \to \mathrm{WO}(X))$ *then*

$$\exists Y\,(\mathrm{WO}(Y) \wedge \forall X\,(X \in A \to |X| \leq |Y|)).$$

PROOF. By lemmas V.2.9 and V.6.2, $\mathsf{ATR}_0$ proves the $\Sigma^1_1$ bounding principle. Hence $\mathsf{ATR}_0$ proves assertion 2.

For the converse, assume 2. Given $\mathrm{WO}(X_0)$ and $\mathrm{WO}(X_1)$, consider the $\Sigma^1_1$ formula $\varphi(X) \equiv (X = X_0 \vee X = X_1)$. By theorem V.1.7 let $A$ be an analytic code such that $\forall X\,(X \in A \leftrightarrow (X = X_0 \vee X = X_1))$. By 2 there exists $Y$ such that $\mathrm{WO}(Y) \wedge |X_0| \leq |Y| \wedge |X_1| \leq |Y|$. It follows that $X_0$ and $X_1$ are comparable. Thus we have CWO. By V.6.8 we have $\mathsf{ATR}_0$. This completes the proof. □

REMARK V.6.10. Girard [90] (see Hirst [121, theorem 2.6]) has shown that $\mathsf{ACA}_0$ is equivalent over $\mathsf{RCA}_0$ to the statement that $\mathrm{WO}(X)$ implies $\mathrm{WO}(Y)$, $|Y| = 2^{|X|}$. See also Hirst [122].

**Notes for §V.6.** Early versions of theorem V.6.8 are due to Steel [256, chapter I] and Friedman [68, 69] (see also [62, chapter II]). Recent refinements are due to Friedman/Hirst [74, 75] and Shore [223]. See also Hirst [119, 120, 121].

## V.7. Countable Abelian Groups

In this section we shall show that $\mathsf{ATR}_0$ is equivalent over $\mathsf{RCA}_0$ to some well known theorems concerning countable reduced Abelian groups.

Let $G$ be a countable Abelian group, and let $p$ be a prime number. $G$ is a *p-group* if for every $a \in G$ we have $p^n a = 0$ for some $n \in \mathbb{N}$. A key theorem in the classification of countable Abelian $p$-groups is Ulm's theorem, which is based on the following arithmetical transfinite recursion: $G_0 = G$, $G_{\alpha+1} = pG_\alpha$, and $G_\delta = \bigcap_{\alpha<\delta} G_\alpha$ for limit ordinals $\delta$. This recursion ends with the least $\beta$ such that $G_\beta = G_{\beta+1}$. If $G_\beta = 0$, the sequence $\langle G_\alpha : \alpha \leq \beta\rangle$ is called an *Ulm resolution* of $G$. In this case, the *Ulm invariants* of $G$, defined here in a form due to Kaplansky, are the numbers $\dim(P_\alpha/P_{\alpha+1})$, where $P_\alpha = \{a \in G_\alpha : pa = 0\}$ and the dimension is computed as a vector space over the field of integers modulo $p$. Each Ulm invariant is either a natural number or $\infty$, and the sequence of Ulm invariants can be written as $\mathrm{U}_G(\alpha) = \dim(P_\alpha/P_{\alpha+1})$, $\alpha < \beta$. *Ulm's theorem* states that two countable reduced Abelian $p$-groups are isomorphic if and only if they have the same Ulm invariants.

In one formulation, Ulm's theorem does not even require arithmetical comprehension:

THEOREM V.7.1. *The following is provable in* $\mathsf{RCA}_0$. *If $G$ and $H$ are countable reduced Abelian $p$-groups with Ulm resolutions $\langle G_\alpha : \alpha \leq \beta\rangle$ and $\langle H_\alpha : \alpha \leq \beta\rangle$ respectively, and if $\mathrm{U}_G(\alpha) = \mathrm{U}_H(\alpha)$ for all $\alpha < \beta$, then $G \cong H$, i.e., $G$ and $H$ are isomorphic.*

PROOF. Richman's constructive proof of Ulm's theorem [205] goes through in $\mathsf{RCA}_0$. □

From V.7.1 it may appear that Ulm's theorem does not require strong set existence axioms. However, the hypothesis of this particular formulation of Ulm's theorem is already very strong, since it implies that the given group $G$ has an Ulm resolution. We shall see that the existence of Ulm resolutions is equivalent to arithmetical transfinite recursion over $\mathsf{RCA}_0$. We shall also see that a certain weak sounding consequence of Ulm's theorem is likewise equivalent to $\mathsf{ATR}_0$ over $\mathsf{RCA}_0$.

We first prove a lemma concerning uniqueness of Ulm resolutions.

LEMMA V.7.2. *The following is provable in* $\mathsf{ACA}_0$. *If $\langle G_\alpha : \alpha \leq \beta\rangle$ and $\langle G'_\alpha : \alpha \leq \beta'\rangle$ are two Ulm resolutions of a countable reduced Abelian $p$-group $G$, then there is an isomorphism of countable well orderings $f : \beta \cong \beta'$ such that $G_\alpha = G'_{f(\alpha)}$ for all $\alpha \leq \beta$.*

PROOF. By arithmetical induction along $\beta$, we easily prove

$$\forall \alpha \leq \beta\, \exists \gamma \leq \beta'\, G_\alpha = G'_\gamma.$$

Symmetrically we also have

$$\forall \gamma \leq \beta'\, \exists \alpha \leq \beta\, G'_\gamma = G_\alpha.$$

Define $f$ by $f(\alpha) = \gamma$ if and only if $G_\alpha = G'_\gamma$. It is easy to see that this works. □

An Abelian group $H$ is said to be a *direct summand* of an Abelian group $G$ if there exists an Abelian group $K$ such that $G \cong H \oplus K$. Let us define a countable Abelian $p$-group $G$ to be *fat* if it has an Ulm resolution $\langle G_\alpha : \alpha \leq \beta\rangle$ such that $\mathrm{U}_G(\alpha) = \infty$ for all $\alpha < \beta$.

The main result of this section is:

THEOREM V.7.3 ($\mathsf{ATR}_0$ and Ulm resolutions). *The following statements are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Arithmetical transfinite recursion.*
2. *Every countable reduced Abelian $p$-group has an Ulm resolution.*
3. *If $G$ and $H$ are fat countable Abelian $p$-groups, then either $G$ is a direct summand of $H$ or $H$ is a direct summand of $G$.*

PROOF. We first prove $1 \to 2$, using the method of pseudohierarchies (§V.4). Assume $\mathsf{ATR}_0$ and let $G$ be a countable reduced Abelian $p$-group. We claim that there exists an Ulm resolution of $G$. Suppose

otherwise, and define $\langle G_\alpha : \alpha \leq \beta \rangle$ to be a *pseudoresolution* if $\beta$ is a linear ordering and $pG_{\alpha_1} \supseteq G_{\alpha_2}$ for all $\alpha_1 < \alpha_2 \leq \beta$, and $G_\beta \neq 0$. By arithmetical transfinite recursion, every countable well ordering carries a pseudoresolution. The property of being a linear ordering which carries a pseudoresolution is $\Sigma^1_1$; hence there exists a linear ordering $\beta$ which is not a well ordering but carries a pseudoresolution. Let $\beta > \alpha_0 > \alpha_1 > \dots$ be a descending sequence through $\beta$. Define $H_n = G_{\alpha_n}$ where $\langle G_\alpha : \alpha \leq \gamma \rangle$ is the pseudoresolution. Thus $H_n \subseteq pH_{n+1}$ for all $n \in \mathbb{N}$. Hence $H = \bigcup_{n \in \mathbb{N}} H_n$ is a divisible subgroup of $G$, and clearly $H \neq 0$. Hence $G$ is not reduced. This contradiction implies that $G$ has an Ulm resolution. Thus we have proved $1 \to 2$.

Next we prove $2 \to 3$. Our first claim is that 2 implies arithmetical comprehension. Reasoning in $\mathsf{RCA}_0$, let $f : \mathbb{N} \to \mathbb{N}$ be one-to-one. Let $G$ be an Abelian group with generators $x_n$, $y_n$, $n \in \mathbb{N}$, and relations $px_n = 0$ and $py_n = x_{f(n)}$. The elements of $G$ can be written in normal form as $\sum_{i \in I} k_i x_i + \sum_{j \in J} l_j y_j$ where $0 < k_i < p$, $0 < l_j < p$, and $I$ and $J$ are finite subsets of $\mathbb{N}$. Thus $G$ exists in $\mathsf{RCA}_0$. Clearly any Ulm resolution of $G$ is of length 2. By V.7.3.2, let $\langle G_0, G_1, G_2 \rangle$ be an Ulm resolution of $G$. We have $G_0 = G$, $G_1 = pG$, and $G_2 = 0$. It is easy to check that $n \in \operatorname{rng}(f)$ if and only if $x_n \in G_1$. Thus $\operatorname{rng}(f)$ exists. By lemma III.1.3 this gives arithmetical comprehension.

Now suppose $G$ and $H$ are fat Abelian $p$-groups with Ulm resolutions $\langle G_\alpha : \alpha \leq \beta_1 \rangle$ and $\langle H_\alpha : \alpha \leq \beta_2 \rangle$, respectively. Define

$$K = G \oplus H = \{(a, b) : a \in G, b \in H\}.$$

Clearly $K$ is reduced, so by our assumption V.7.3.2, $K$ has an Ulm resolution $\langle K_\alpha : \alpha \leq \beta_3 \rangle$. Define $\pi_1(K_\alpha) = \{a : \exists b (a, b) \in K_\alpha\}$. Then $\langle \pi_1(K_\alpha) : \alpha \leq \beta_3 \rangle$ exists by arithmetical comprehension, and clearly $\langle \pi_1(K_\alpha) : \alpha \leq \gamma_1 \rangle$ is an Ulm resolution of $G$ for some $\gamma_1 \leq \beta_3$. By lemma V.7.2 there exists an isomorphism $f : \beta_1 \cong \gamma_1$ such that $G_\alpha = \pi_1(K_{f(\alpha)})$ for all $\alpha \leq \beta_1$. Similarly, there exists an isomorphism $g : \beta_2 \cong \gamma_2 \leq \beta_3$ such that $H_\alpha \cong \pi_2(K_{g(\alpha)})$ for all $\alpha \leq \beta_2$. Thus $\langle G_\alpha \oplus H_\alpha : \alpha \leq \beta_3 \rangle$ is an Ulm resolution of $K$. By lemma V.7.2 it follows that $K_\alpha = G_\alpha \oplus H_\alpha$ and hence $\mathrm{U}_K(\alpha) = \infty$ for all $\alpha \leq \beta_3$. Moreover $\beta_3 = \max(\gamma_1, \gamma_2)$, say $\beta_3 = \gamma_1$, so by theorem V.7.1 it follows that $G \cong K = G \oplus H$, i.e., $H$ is a direct summand of $G$. This completes the proof of $2 \to 3$.

It remains to prove $3 \to 1$. Again, we shall first prove that 3 implies arithmetical comprehension. We shall then complete the argument by showing that 3 implies CWO.

Reasoning in $\mathsf{RCA}_0$, let $\beta$ be any countable ordinal. We construct a reduced Abelian $p$-group $G(\beta)$ of Ulm rank $\beta$, as follows. Define an *unsecured sequence* to be a finite sequence $s = \langle \alpha_1, \dots, \alpha_n \rangle$, $\beta > \alpha_1 > \dots > \alpha_n$, $n \in \mathbb{N}$. The generators of $G(\beta)$ are $x_s$ for all unsecured sequences $s$. The relations are $px_t = x_s$, $t = s^\frown\langle\alpha\rangle$, $t$ unsecured, and

$x_{\langle\rangle} = 0$. The elements of $G(\beta)$ have the normal form $\sum_{s\in S} m_s x_s$ where $s \neq \langle\rangle$, $0 < m_s < p$, and $S$ is finite. Put $\mu(x_s) = \alpha_n$ if $s = \langle\alpha_1, \ldots, \alpha_n\rangle$, $n \geq 1$, and for $a = \sum_s m_s x_s \in G(\beta)$ put $\mu(a) = \min_s \mu(x_s)$. Note that $\mu(0)$ is undefined. It is easy to see that $G(\beta)$ is a reduced Abelian $p$-group with canonical Ulm resolution $\langle G_\alpha : \alpha \leq \beta\rangle$ where $G_\alpha = \{a : \mu(a) \geq \alpha\} \cup \{0\}$. In particular $x_{\langle\alpha\rangle} \in G_\alpha \setminus G_{\alpha+1}$ and $\mathrm{U}_{G(\beta)}(\alpha) \geq 1$.

Let $H(\beta)$ be the direct sum of countably many copies of $G(\beta)$. Then $H(\beta)$ inherits an Ulm resolution from $G(\beta)$. Moreover $\mathrm{U}_{H(\beta)}(\alpha) = \infty$ for all $\alpha < \beta$, i.e., $H(\beta)$ is fat.

LEMMA V.7.4. *It is provable in* $\mathsf{RCA}_0$ *that* V.7.3.3 *implies arithmetical comprehension*.

PROOF. Reasoning in $\mathsf{RCA}_0$, let $f : \mathbb{N} \to \mathbb{N}$ be one-to-one. Define $m \prec n \equiv f(m) < f(n)$, and let $\omega_0$ be (the ordinal encoded by) the countable well ordering $\mathbb{N}, \prec$. Note that for all $\alpha < \omega_0$, $\{\beta : \beta < \alpha\}$ is finite, by bounded $\Sigma^0_1$ comprehension. Let $\omega$ be (the ordinal encoded by) the countable well ordering $\mathbb{N}, <$, i.e., the standard ordering of $\mathbb{N}$. Consider the groups $H(\omega_0)$ and $H(\omega + 1)$. By our assumption V.7.3.3, one is a direct summand of the other. In $H(\omega + 1)$ there is a nonzero element, $x_{\langle\omega\rangle}$, which is divisible by $p^n$ for all $n \in \mathbb{N}$. We claim that in $H(\omega_0)$ there is no such element. For if $p^n \sum_{t\in T} n_t x_t = \sum_{s\in S} m_s x_s$, then each $s \in S$ is an initial segment of some $t \in T$, and $\mathrm{lh}(t) = \mathrm{lh}(s) + n$. Since $t$ is unsecured, it follows that $\mu(x_s)$ has at least $n$ elements preceding it. This proves our claim. It follows that $H(\omega + 1)$ is not a direct summand of $H(\omega_0)$. Hence $H(\omega_0)$ is a direct summand of $H(\omega + 1)$. Define $g : \omega_0 \to \omega$ by $g(n) =$ the least $m$ such that $x_{\langle n\rangle} \in H_m \setminus H_{m+1}$, where $\langle H_m : m \leq \omega + 1\rangle$ is the canonical Ulm resolution of $H(\omega + 1)$. Then $g$ is an isomorphism of $\omega_0$ onto $\omega$. Define $h : \mathbb{N} \to \mathbb{N}$ by $h(x) =$ least $n$ such that $f(n) > x$. Then $x \in \mathrm{rng}(f)$ if and only if $\exists y \prec h(x)\,(f(y) = x)$, if and only if $\exists z < g(h(x))\,(f(g^{-1}(z)) = x)$. Thus $\mathrm{rng}(f)$ exists by $\Delta^0_1$ comprehension. By lemma III.1.3 this gives arithmetical comprehension. □

Now let $\beta_1$ and $\beta_2$ be two ordinals. Consider the canonical Ulm resolutions $\langle H_\alpha(\beta_1) : \alpha \leq \beta_1\rangle$ and $\langle H_\alpha(\beta_2) : \alpha \leq \beta_2\rangle$ of $H(\beta_1)$ and $H(\beta_2)$ respectively. $H(\beta_1)$ and $H(\beta_2)$ are fat, so by V.7.3.3 we have, say, $H(\beta_1)$ is a direct summand of $H(\beta_2)$. Put $K_\alpha = H(\beta_1) \cap H_\alpha(\beta_2)$, and let $\beta_0 \leq \beta_2$ be the least $\alpha$ such that $K_\alpha = 0$. Then $\langle K_\alpha : \alpha \leq \beta_0\rangle$ is another Ulm resolution of $H(\beta_1)$. By lemma V.7.2 this gives an isomorphism $f : \beta_1 \cong \beta_0$. Thus we have comparability of countable well orderings, CWO. Hence by theorem V.6.8 we get arithmetical transfinite recursion. This completes the proof of $3 \to 1$ and of theorem V.7.3. □

REMARK V.7.5. In addition to statements such as V.7.3.2 and V.7.3.3, there are other statements equivalent to $\mathsf{ATR}_0$ that are purely about countable Abelian groups, with no mention of ordinal numbers or Ulm invariants. The following exercise presents one such result.

EXERCISE V.7.6. Show that the following statement is equivalent over $\mathsf{ACA}_0$ to $\mathsf{ATR}_0$: For any countable reduced Abelian $p$-groups $G$ and $H$, there is a common direct summand $K$ such that every common direct summand is embeddable in $K$.

REMARK V.7.7 (a conjecture of Friedman). Consider the following statement S: If $G$ and $H$ are two countable reduced Abelian $p$-groups, and if each of $G$ and $H$ is a direct summand of the other, then $G$ is isomorphic to $H$. Note that S is easily proved in $\mathsf{ATR}_0$ as a consequence of Ulm's theorem. Note also that S is a simple statement about countable Abelian groups and does not explicitly mention ordinal numbers or Ulm invariants (compare remark V.7.5). Friedman has conjectured that S is equivalent over $\mathsf{ACA}_0$ to $\mathsf{ATR}_0$.

**Notes for §V.7.** A nice exposition of Ulm's theorem is in Kaplansky [136]. The main results of this section are due to Friedman/Simpson/Smith [78]. Exercise V.7.6 is due to Friedman (unpublished manuscript, May 4, 1986).

## V.8. $\Sigma^0_1$ and $\Delta^0_1$ Determinacy

In this section we show that $\mathsf{ATR}_0$ is just strong enough to prove a certain special case of the so-called axiom of determinacy.

Recall that the *Baire space* $\mathbb{N}^{\mathbb{N}}$ is the space of all total functions $f : \mathbb{N} \to \mathbb{N}$. Recall the notation

$$f[n] = \langle f(0), f(1), \ldots, f(n-1)\rangle \in \mathrm{Seq}.$$

Define $\mathrm{Seq}_0 = \{\sigma \in \mathrm{Seq} : \mathrm{lh}(\sigma) \text{ is even}\}$ and $\mathrm{Seq}_1 = \{\sigma \in \mathrm{Seq} : \mathrm{lh}(\sigma) \text{ is odd}\}$. A 0-*strategy* is a function $S_0 : \mathrm{Seq}_0 \to \mathbb{N}$. A 1-*strategy* is a function $S_1 : \mathrm{Seq}_1 \to \mathbb{N}$. If $S_0$ is a 0-strategy and $S_1$ is a 1-strategy, let $S_0 \otimes S_1$ be the function $f : \mathbb{N} \to \mathbb{N}$ defined by $f(2k) = S_0(f[2k])$, $f(2k+1) = S_1(f[2k+1])$.

The *axiom of determinacy* is the assertion that for all $\mathcal{F} \subseteq \mathbb{N}^{\mathbb{N}}$ either $\exists S_0 \forall S_1 (S_0 \otimes S_1 \in \mathcal{F})$ or $\exists S_1 \forall S_0 (S_0 \otimes S_1 \notin \mathcal{F})$. The intuitive idea behind the axiom of determinacy is as follows. Consider an infinite game $G_{\mathcal{F}}$ between two players, 0 and 1. The rules of the game are that player 0 picks $f(0)$, then player 1 picks $f(1), \ldots$, then player 0 picks $f(2k)$, then player 1 picks $f(2k+1)$, then $\ldots$. Finally player 0 wins if $f \in \mathcal{F}$, and player 1 wins if $f \notin \mathcal{F}$. The axiom of determinacy asserts that one player or the other has a winning strategy.

The axiom of determinacy is generally regarded as false. Nevertheless, the axiom of determinacy is the basis of an intricate theory known as *modern descriptive set theory*. In this theory, some of the known results concerning Borel and analytic sets are generalized to projective and hyperprojective classes, assuming the axiom of determinacy.

Modern descriptive set theory is a generalization of classical descriptive set theory, and classical descriptive set theory is a branch of ordinary mathematics. Therefore, from the viewpoint of the Main Question of this book, it is of interest to investigate the extent to which special cases of the axiom of determinacy are provable in subsystems of second order arithmetic.

The main result of this section is that $\mathsf{ATR}_0$ is just strong enough to prove all instances of the axiom of determinacy in which the set $\mathcal{F} \subseteq \mathbb{N}^{\mathbb{N}}$ is open or clopen, i.e., $\Sigma^0_1$ or $\Delta^0_1$ definable. We formalize this as follows:

DEFINITION V.8.1 ($\Sigma^0_1$ and $\Delta^0_1$ determinacy). By $\Sigma^0_1$ (respectively $\Pi^0_1$) *determinacy* we mean the scheme

$$\exists S_0\, \forall S_1\, \varphi(S_0 \otimes S_1) \vee \exists S_1\, \forall S_0\, \neg\varphi(S_0 \otimes S_1)$$

where $\varphi$ is $\Sigma^0_1$ (respectively $\Pi^0_1$). By $\Delta^0_1$ *determinacy* we mean the scheme

$$\forall f\, (\varphi(f) \leftrightarrow \psi(f)) \rightarrow (\exists S_0\, \forall S_1\, \varphi(S_0 \otimes S_1) \vee \exists S_1\, \forall S_0\, \neg\varphi(S_0 \otimes S_1))$$

where $\varphi$ and $\psi$ are $\Sigma^0_1$ and $\Pi^0_1$, respectively. The schemes of $\Sigma^i_k$, $\Pi^i_k$, and $\Delta^i_k$ determinacy, $i < 2$, $1 \leq k \leq \infty$, are defined similarly.

(In the above definition, $S_0$ and $S_1$ range over 0-strategies and 1-strategies respectively, and $f$ ranges over total functions from $\mathbb{N}$ into $\mathbb{N}$.)

THEOREM V.8.2. $\mathsf{ATR}_0$ *proves* $\Sigma^0_1$ *determinacy.*

PROOF. We reason in $\mathsf{ATR}_0$. Let $\varphi(f)$ be a $\Sigma^0_1$ formula. We can write $\varphi(f)$ in normal form as $\varphi(f) \equiv \exists n\, \theta(f[n])$ where $\theta$ is arithmetical (see lemma V.1.4). By arithmetical comprehension let $W$ be the set of all $\sigma \in \mathrm{Seq}_0$ such that $\exists n\, (n \leq \mathrm{lh}(\sigma) \wedge \theta(\sigma[n]))$. Thus $\forall f(\varphi(f) \leftrightarrow \exists k\, (f[2k] \in W))$. Intuitively, $W$ is the set of positions at which player 0 has "already won". It is to be proved that

$$\exists S_0\, \forall S_1\, \exists k\, ((S_0 \otimes S_1)[2k] \in W) \vee \exists S_1\, \forall S_0\, \forall k\, ((S_0 \otimes S_1)[2k] \notin W).$$

We proceed much as in the proof of the perfect set theorem in $\mathsf{ATR}_0$, theorem V.4.3. By arithmetical transfinite recursion, there exists for each countable well ordering $X$ a sequence of sets $\langle W_j : j \in \mathrm{field}(X)\rangle$ such that

$$\forall j\, \forall \sigma\, (\sigma \in W_j \leftrightarrow (\sigma \in W \vee \exists m\, \forall n\, \exists i\, (i <_X j \wedge \sigma^\frown\langle m, n\rangle \in W_i))). \tag{$*$}$$

The intuitive idea here is that to each countable ordinal $\beta$ we associate a set $W_\beta \subseteq \mathrm{Seq}_0$ by $W_0 = W$, $W_\beta = \{\sigma : \exists m\, \forall n\, (\sigma^\frown\langle m, n\rangle \in \bigcup_{\alpha<\beta} W_\alpha)\}$ for $\beta > 0$. Thus each $\sigma \in W_\beta$ is a "winning position of order $\beta$" for player 0. The proof splits into two cases.

Case 1. There exists a countable well ordering $X$ and a sequence of sets $\langle W_j : j \in \mathrm{field}(X)\rangle$ such that $(*)$ holds and in addition $\langle\rangle \in W_l$ for some $l \in \mathrm{field}(X)$.

In this case, for each $\sigma \in W_l$, let $g(\sigma)$ be the unique $j \leq_X l$ such that $\sigma \in W_j \wedge \forall i\,(i <_X j \to \sigma \notin W_i)$. For each $\sigma \in \mathrm{Seq}_0$ define $S_0(\sigma) = 0$ if $\sigma \in W$ or if $\sigma \notin W_l$, otherwise $S_0(\sigma) =$ the least $m$ such that $\forall n\,\exists i\,(i <_X g(\sigma) \wedge \sigma^\frown\langle m,n\rangle \in W_i)$. This $m$ exists by $(*)$. Thus $S_0$ is a 0-strategy.

We claim that $S_0$ is a winning strategy for player 0, i.e.,

$$\forall S_1\,\exists k\,((S_0 \otimes S_1)[2k] \in W).$$

To see this, consider any 1-strategy $S_1$ and put $f = S_0 \otimes S_1$. By case hypothesis, $\langle\rangle \in W_l$. By choice of $S_0$, $f[2k] \in W_l$ implies $f[2k+2] \in W_l$. Thus by induction $f[2k] \in W_l$ for all $k$. Also, by choice of $S_0$, $f[2k] \notin W$ implies $g(f[2k+2]) <_X g(f[2k])$. Since $X$ is a well ordering, there must exist $k$ such that $f[2k] \in W$. This proves the claim.

Case 2. Assume that the hypothesis of case 1 does not hold.

In this case we use the method of pseudohierarchies. By lemma V.4.12 (or by a direct argument as in case 2 of the proof of theorem V.4.3), there exists a countable linear ordering $X$ and a sequence of sets $\langle W_j : j \in \mathrm{field}(X)\rangle$ such that $(*)$ holds and in addition $\forall j\,(j \in \mathrm{field}(X) \to \langle\rangle \notin W_j)$ and $X$ is not a well ordering. Let $g : \mathbb{N} \to \mathrm{field}(X)$ be a fixed descending sequence through $X$, i.e., $g(k+1) <_X g(k)$ for all $k$. For each $\sigma \in \mathrm{Seq}_1$ of length $2k+1$ define $S_1(\sigma) =$ least $n$ such that $\sigma^\frown\langle n\rangle \notin W_{g(k+1)}$ if such an $n$ exists, otherwise $S_1(\sigma) = 0$. Thus $S_1$ is a 1-strategy.

We claim that $S_1$ is a winning strategy for player 1, i.e.,

$$\forall S_0\,\forall k\,((S_0 \otimes S_1)[2k] \notin W).$$

To see this, consider a 0-strategy $S_0$ and put $f = S_0 \otimes S_1$. By case hypothesis, $\langle\rangle \notin W_{g(0)}$. If $f[2k] \notin W_{g(k)}$, then by $(*)$ we have $\forall m\,\exists n\,\forall i\,(i <_X g(k) \to f[2k]^\frown\langle m,n\rangle \notin W_i)$. Hence by choice of $S_1$ we have $f[2k+2] \notin W_{g(k+1)}$. Thus by induction $f[2k] \notin W_{g(k)}$ for all $k$. In particular $\forall k\,(f[2k] \notin W)$ proving our claim.

This completes the proof of theorem V.8.2. □

As a consequence of $\Sigma^0_1$ determinacy in $\mathsf{ATR}_0$, we obtain a form of the axiom of choice in $\mathsf{ATR}_0$:

THEOREM V.8.3 ($\Sigma^1_1$ axiom of choice). $\mathsf{ATR}_0$ *proves the* $\Sigma^1_1$ *axiom of choice, i.e., the scheme*

$$\forall k\,\exists X\,\varphi(k,X) \to \exists Y\,\forall k\,\varphi(k,(Y)_k)$$

*where* $\varphi$ *is any* $\Sigma^1_1$ *formula and* $(Y)_k = \{i : (i,k) \in Y\}$.

PROOF. We reason in $\mathsf{ATR}_0$. By theorem V.1.7′ it suffices to prove: *For any sequence of trees* $\langle T_k : k \in \mathbb{N}\rangle$ *such that* $\forall k\,(T_k$ *has a path*$)$, *there exists a sequence* $\langle g_k : k \in \mathbb{N}\rangle$ *such that* $\forall k\,(g_k$ *is a path through* $T_k)$. We shall obtain this as a consequence of $\Sigma^0_1$ determinacy.

In the intuitive game-theoretic terminology, consider the following $\Sigma^0_1$ game. Player 0 chooses $k$, then player 1 chooses $g(0), g(1), \ldots$. Player

1 wins if and only if $g$ is a path through $T_k$. Since $\forall k$ ($T_k$ has a path), player 0 cannot have a winning strategy. Hence by $\Sigma^0_1$ determinacy there exists a winning strategy for player 1. This strategy provides the desired choice function.

Formally, let $\varphi(f)$ be the following $\Sigma^0_1$ formula:

$$\exists j\,(\langle f(1), f(3), \ldots, f(2j-1)\rangle \notin T_{f(0)}).$$

We claim that $\forall S_0\,\exists S_1\,\neg\varphi(S_0 \otimes S_1)$. To see this, let $S_0$ be given. Put $k = S_0(\langle\rangle)$ and let $g$ be any path through $T_k$. Define $S_1(\sigma) = g(j)$ for all $\sigma$ of length $2j+1$. Put $f = S_0 \otimes S_1$. Clearly $f(0) = k$ and $f(2j+1) = g(j)$ for all $j$. Since $g$ is a path through $T_k$, we have $\forall j\,(\langle f(1), f(3), \ldots, f(2j-1)\rangle \in T_{f(0)})$, i.e., $\neg\varphi(f)$. This proves our claim. Hence by $\Sigma^0_1$ determinacy there exists $S_1$ such that $\forall S_0\,\neg\varphi(S_0 \otimes S_1)$. Define a sequence of functions $\langle g_k : k \in \mathbb{N}\rangle$ by

$$g_k(j) = S_1(\langle k, \underbrace{0, \ldots, 0}_{2j}\rangle).$$

We claim that $g_k$ is a path through $T_k$. To see this, define $S_0(\langle\rangle) = k$ and $S_0(\sigma) = 0$ for all other $\sigma \in \mathrm{Seq}_0$. Put $f = S_0 \otimes S_1$. Then $f(2j+1) = g_k(j)$ for all $j$. We have $\neg\varphi(S_0 \otimes S_1)$, i.e., $\neg\varphi(f)$, i.e.,

$$\neg\exists j\,(\langle g_k(0), g_k(1), \ldots, g_k(j-1)\rangle \notin T_k),$$

i.e., $g_k$ is a path through $T_k$. This completes the proof. □

REMARK V.8.4 ($\Sigma^1_1$ choice versus $\mathsf{ATR}_0$). The $\Sigma^1_1$ axiom of choice is not equivalent to $\mathsf{ATR}_0$. For instance, the $\omega$-model HYP (proposition V.2.6) satisfies the $\Sigma^1_1$ axiom of choice but does not satisfy $\mathsf{ATR}_0$. It is also true that $\mathsf{ATR}_0$ proves the existence of a countable $\omega$-model of $\mathsf{ACA}_0$ plus the $\Sigma^1_1$ axiom of choice. For more information on models of the $\Sigma^1_1$ axiom of choice, see §§VIII.3, VIII.4, VIII.5, and IX.4.

We now turn to the reversal of $\Sigma^0_1$ determinacy. We shall in fact show that $\Delta^0_1$ determinacy implies arithmetical transfinite recursion. We begin with:

LEMMA V.8.5. *It is provable in* $\mathsf{RCA}_0$ *that* $\Delta^0_1$ *determinacy implies arithmetical comprehension.*

PROOF. Reasoning in $\mathsf{RCA}_0$, assume $\Delta^0_1$ determinacy. Instead of arithmetical comprehension we shall prove the equivalent statement III.1.3.3. Let $g : \mathbb{N} \to \mathbb{N}$ be given. We shall prove the existence of a set $X$ such that $\forall k\,(k \in X \leftrightarrow \exists m\,(g(m) = k))$.

In the intuitive game-theoretic terminology, consider the following game of length 3. Player 0 chooses $k$, then player 1 chooses $n$, then player 0 chooses $m$. Player 0 wins if and only if $g(n) \neq k$ and $g(m) = k$. Clearly player 0 cannot have a winning strategy. Hence by $\Delta^0_1$ determinacy

player 1 has a winning strategy. The desired set $X$ then exists by $\Delta^0_1$ comprehension, using this strategy as a parameter.

Formally, let $\varphi(f)$ be the following $\Sigma^0_1$ or $\Pi^0_1$ formula:

$$g(f(1)) \neq f(0) \wedge g(f(2)) = f(0).$$

We claim that $\forall S_0\, \exists S_1\, \neg\varphi(S_0 \otimes S_1)$. Given $S_0$, put $k = S_0(\langle\rangle)$. Let $n$ be such that $g(n) = k$ if such an $n$ exists, otherwise let $n = 0$. Consider any $S_1$ such that $S_1(\langle k\rangle) = n$. Put $m = S_0(\langle k, n\rangle)$. Then $g(n) = k \vee g(m) \neq k$, i.e., $\neg\varphi(S_0 \otimes S_1)$. This proves our claim. Hence by $\Delta^0_1$ determinacy there exists $S_1$ such that $\forall S_0\, \neg\varphi(S_0 \otimes S_1)$. We claim that

$$\forall m\, \forall k\, (g(m) = k \rightarrow g(S_1(\langle k\rangle)) = k).$$

If not, let $m$ and $k$ be such that $g(m) = k$ and $g(S_1(\langle k\rangle)) \neq k$. Put $n = S_1(\langle k\rangle)$ and consider any $S_0$ such that $S_0(\langle\rangle) = k$ and $S_0(\langle k, n\rangle) = m$. Then $g(n) \neq k \wedge g(m) = k$, i.e., $\varphi(S_0 \otimes S_1)$. This contradiction proves our claim. Hence

$$\forall k\, (\exists m\, (g(m) = k) \leftrightarrow g(S_1(\langle k\rangle)) = k).$$

Applying $\Delta^0_1$ comprehension we get $\exists X\, \forall k\, (k \in X \leftrightarrow \exists m\, (g(m) = k))$. Hence by lemma III.1.3 we have arithmetical comprehension. This completes the proof of lemma V.8.5. □

In order to prove that $\Delta^0_1$ determinacy implies arithmetical transfinite recursion, we consider the following family of $\Delta^0_1$ games. Let $X$ and $Y$ be countable linear orderings. Assume that at least one of $X$ and $Y$ is a well ordering. Let $G(X, Y)$ be the game in which player 0 builds a descending sequence $f(0) >_X f(2) >_X \cdots$ through $X$ and player 1 builds a descending sequence $f(1) >_Y f(3) >_Y \cdots$ through $Y$. The winner of $G(X, Y)$ is that player whose descending sequence keeps going the longest. Clearly 0 has a winning strategy for $G(X, Y)$ whenever $\neg\mathrm{WO}(X)$. Also, if 0 has a winning strategy $S_0$ for $G(X, Y)$, then 1 has a winning strategy for $G(Y, X)$, namely, he disregards 0's initial move $f(0)$ and thereafter plays $S_0$. We formalize this as follows:

LEMMA V.8.6. *The following is provable in* $\mathsf{RCA}_0$. *Assume*

$$\mathrm{LO}(X) \wedge \mathrm{LO}(Y) \wedge (\mathrm{WO}(X) \vee \mathrm{WO}(Y)).$$

*Let* $\varphi(f, X, Y)$ *be the* $\Sigma^0_1$ *formula*

$$\exists j\, (f(2j+3) \not<_Y f(2j+1) \wedge \forall i\, (i \leq j \rightarrow f(2i+2) <_X f(2i))).$$

*Let* $\psi(f, X, Y)$ *be the* $\Pi^0_1$ *formula*

$$\neg\exists j\, (f(2j+2) \not<_X f(2j) \wedge \forall i\, (i < j \rightarrow f(2i+3) <_Y f(2i+1))).$$

*Then*:

1. $\forall f\, (\varphi(f, X, Y) \leftrightarrow \psi(f, X, Y))$.
2. $\neg\mathrm{WO}(X) \rightarrow \exists S_0\, \forall S_1\, \varphi(S_0 \otimes S_1, X, Y)$.
3. $\exists S_0\, \forall S_1\, \varphi(S_0 \otimes S_1, X, Y) \rightarrow \exists S_1\, \forall S_0\, \neg\varphi(S_0 \otimes S_1, Y, X)$.

PROOF. 1. Let $f : \mathbb{N} \to \mathbb{N}$ be given. Since $\mathrm{WO}(X) \vee \mathrm{WO}(Y)$ there must exist $i$ such that $f(2i+2) \not<_X f(2i) \vee f(2i+3) \not<_Y f(2i+1)$. Let $j$ be the least such $i$. If $f(2j+2) <_X f(2j)$ then we have $\varphi(f, X, Y) \wedge \psi(f, X, Y)$. If $f(2j+2) \not<_X f(2j)$ then we have $\neg\varphi(f, X, Y) \wedge \neg\psi(f, X, Y)$.

2. Let $g : \mathbb{N} \to \mathrm{field}(X)$ be a descending sequence through $X$. Define $S_0(\sigma) = g(j)$ for all $\sigma$ of length $2j$. Given any 1-strategy $S_1$, put $f = S_0 \otimes S_1$. Then $f(2j+2) = g(j+1) <_X g(j) = f(2j)$ for all $j$. Hence $\psi(f, X, Y)$. Hence $\varphi(f, X, Y)$, i.e., $\varphi(S_0 \otimes S_1, X, Y)$, in view of part 1.

3. Let $S_0$ be such that $\forall S_1\, \varphi(S_0 \otimes S_1, X, Y)$. Define

$$S_1'(\sigma) = S_0(\langle \sigma(1), \ldots, \sigma(2j) \rangle)$$

for all $\sigma$ of length $2j+1$. We claim that $\forall S_0' \neg\varphi(S_0' \otimes S_1', Y, X)$. To see this, let $S_0'$ be given. Set $k = S_0'(\langle\rangle)$ and define $S_1(\sigma) = S_0'(\langle k \rangle^\frown \sigma)$ for all $\sigma \in \mathrm{Seq}_1$. Put $f = S_0 \otimes S_1$ and $f' = S_0' \otimes S_1'$. Beginning with $f'(0) = k$ we have inductively

$$\begin{aligned} f'(2j+1) &= S_1'(f'[2j+1]) = S_0(\langle f'(1), \ldots, f'(2j) \rangle) \\ &= S_0(\langle f(0), \ldots, f(2j-1) \rangle) = S_0(f[2j]) = f(2j) \end{aligned}$$

and

$$\begin{aligned} f(2j+1) &= S_1(f[2j+1]) = S_0'(\langle k \rangle^\frown f[2j+1]) \\ &= S_0'(\langle k, f(0), \ldots, f(2j) \rangle) = S_0'(f'[2j+2]) = f'(2j+2). \end{aligned}$$

Thus $f(2j) = f'(2j+1)$ and $f(2j+1) = f'(2j+2)$ for all $j$. By assumption $\varphi(S_0 \otimes S_1, X, Y)$, i.e., $\varphi(f, X, Y)$. Let $j$ be such that

$$f(2j+3) \not<_Y f(2j+1) \wedge \forall i\, (i \leq j \to f(2i+2) <_X f(2i)).$$

It follows that

$$f'(2j+4) \not<_Y f'(2j+2) \wedge \forall i\, (i \leq j \to f'(2i+3) <_X f'(2i+1)).$$

Thus $\neg\psi(f, Y, X)$, i.e., $\neg\varphi(f', Y, X)$, i.e., $\neg\varphi(S_0' \otimes S_1', Y, X)$. This proves our claim. The proof of lemma V.8.6 is complete. □

With the above lemmas, we are now ready to prove:

THEOREM V.8.7 ($\mathsf{ATR}_0$ and determinacy). *The following are pairwise equivalent over* $\mathsf{RCA}_0$:

1. *arithmetical transfinite recursion*;
2. $\Sigma^0_1$ *determinacy*;
3. $\Delta^0_1$ *determinacy.*

PROOF. The implication from 1 to 2 has already been proved as theorem V.8.2. The implication from 2 to 3 is trivial. It remains to prove that 3 implies 1. Assume $\Delta^0_1$ determinacy. By lemma V.8.5 we have arithmetical comprehension. We wish to prove arithmetical transfinite recursion. Instead of proving arithmetical transfinite recursion directly, we shall prove the $\Sigma^1_1$ separation principle V.5.1.2. Assume that $\neg\exists k\, (\varphi_1(k) \wedge \varphi_0(k))$ where $\varphi_1(k)$ and $\varphi_0(k)$ are $\Sigma^1_1$. We seek a set $Z \subseteq \mathbb{N}$ such

that $\forall k\,((\varphi_1(k) \to k \in Z) \wedge (\varphi_0(k) \to k \notin Z))$. By theorem V.1.7′ and lemma V.1.3 there exist sequences of countable linear orderings $\langle X_k : k \in \mathbb{N}\rangle$ and $\langle Y_k : k \in \mathbb{N}\rangle$ such that $\forall k\,(\varphi_1(k) \leftrightarrow \neg\mathrm{WO}(X_k))$ and $\forall k\,(\varphi_0(k) \leftrightarrow \neg\mathrm{WO}(Y_k))$. Our assumption $\neg\exists k\,(\varphi_1(k) \wedge \varphi_0(k))$ implies that $\forall k\,(\mathrm{WO}(X_k) \vee \mathrm{WO}(Y_k))$.

In the intuitive game-theoretic terminology, consider the following $\Delta^0_1$ game $G'$. Player 0 chooses $k$, then player 1 chooses $i \in \{0, 1\}$, then players 0 and 1 play $G(X_k, Y_k)$ if $i = 0$, $G(Y_k, X_k)$ if $i = 1$. (The family of $\Delta^0_1$ games $G(X, Y)$ was defined in the discussion preceding lemma V.8.6.) We claim that 0 has no winning strategy for $G'$. To see this, suppose that 0 begins $G'$ by choosing $k$. If 1 has a winning strategy for $G(X_k, Y_k)$, he can win $G'$ by playing $i = 0$ followed by that strategy. If 1 does not have a winning strategy for $G(X_k, Y_k)$, then by $\Delta^0_1$ determinacy, 0 has a winning strategy for $G(X_k, Y_k)$. Hence 1 has a winning strategy for $G(Y_k, X_k)$, so he can win $G'$ by playing $i = 1$ followed by that strategy. In either case, 1 can win $G'$. This proves our claim. Hence, by $\Delta^0_1$ determinacy, 1 has a winning strategy for $G'$. Let $Z$ be the set of all $k$ such that if 0 begins $G'$ by choosing $k$, then 1 responds with $i = 1$ according to his winning strategy. It is easy to see that $Z$ is the desired separating set.

Formally, let $\varphi$ and $\psi$ be as in lemma V.8.6. For each $f : \mathbb{N} \to \mathbb{N}$ define $f'(n) = f(n + 2)$ for all $n$. Let $\varphi'(f)$ be the $\Sigma^0_1$ formula

$$(f(1) = 0 \wedge \varphi(f', X_{f(0)}, Y_{f(0)})) \vee (f(1) = 1 \wedge \varphi(f', Y_{f(0)}, X_{f(0)})) \vee f(1) \geq 2.$$

Let $\psi'(f)$ be the $\Pi^0_1$ formula

$$(f(1) = 0 \wedge \psi(f', X_{f(0)}, Y_{f(0)})) \vee (f(1) = 1 \wedge \psi(f', Y_{f(0)}, X_{f(0)})) \vee f(1) \geq 2.$$

By lemma V.8.6.1 we have $\forall f\,(\varphi'(f) \leftrightarrow \psi'(f))$.

We claim that $\forall S_0\,\exists S_1\,\neg\varphi'(S_0 \otimes S_1)$. To see this, let $S_0$ be given and set $k = S_0(\langle\rangle)$. Case 1: Assume that $\exists S'_1\,\forall S'_0\,\neg\varphi(S'_0 \otimes S'_1, X_k, Y_k)$. Then choose such an $S'_1$ and set $i = 0$. Case 2: Assume that the hypothesis of case 1 does not hold. Then by lemma V.8.6.1 and $\Delta^0_1$ determinacy we have $\exists S'_0\,\forall S'_1\,\varphi(S'_0 \otimes S'_1, X_k, Y_k)$. Hence by lemma V.8.6.3 we have $\exists S'_1\,\forall S'_0\,\neg\varphi(S'_0 \otimes S'_1, Y_k, X_k)$. Choose such an $S'_1$ and set $i = 1$. In either case define $S_1(\sigma) = i$ for $\sigma$ of length 1, $S_1(\sigma) = S'_1(\langle\sigma(2), \ldots, \sigma(2j + 2)\rangle)$ for $\sigma$ of length $2j + 3$, and $S'_0(\sigma) = S_0(\langle k, i\rangle^\frown\sigma)$ for all $\sigma \in \mathrm{Seq}_0$. Thus $S'_0 \otimes S'_1 = (S_0 \otimes S_1)'$ so by choice of $S'_1$ and $i$ we have

$$(i = 0 \wedge \neg\varphi((S_0 \otimes S_1)', X_k, Y_k)) \vee (i = 1 \wedge \neg\varphi((S_0 \otimes S_1)', Y_k, X_k)).$$

Hence $\neg\varphi'(S_0 \otimes S_1)$. This proves our claim.

Hence by $\Delta^0_1$ determinacy there exists $S_1$ such that $\forall S_0\, \neg\varphi'(S_0 \otimes S_1)$. We claim that

$$\forall k\, ((\neg \mathrm{WO}(X_k) \to S_1(\langle k\rangle) = 1) \wedge (\neg \mathrm{WO}(Y_k) \to S_1(\langle k\rangle) = 0)).$$

To see this, let $k$ be given. Define $i = S_1(\langle k\rangle)$ and $S'_1(\sigma) = S_1(\langle k, i\rangle^\frown\sigma)$ for all $\sigma \in \mathrm{Seq}_1$. If $\neg\mathrm{WO}(X_k)$, then by V.8.6.2 let $S'_0$ be such that $\varphi(S'_0 \otimes S'_1, X_k, Y_k)$. Define $S_0(\langle\rangle) = k$ and $S_0(\sigma) = S'_0(\langle\sigma(2), \ldots, \sigma(2j+1)\rangle)$ for $\sigma$ of length $2j+2$. Then $S'_0 \otimes S'_1 = (S_0 \otimes S_1)'$, hence $\varphi((S_0 \otimes S_1)', X_k, Y_k)$. Since $\neg\varphi'(S_0 \otimes S_1)$, we must have $(S_0 \otimes S_1)(1) \neq 0$. Hence $S_1(\langle k\rangle) = (S_0 \otimes S_1)(1) = 1$. On the other hand, if $\neg\mathrm{WO}(Y_k)$, then by V.8.6.2 let $S'_0$ be such that $\varphi(S'_0 \otimes S'_1, Y_k, X_k)$. Defining $S_0$ as before, we have again $S'_0 \otimes S'_1 = (S_0 \otimes S_1)'$, hence this time $\varphi((S_0 \otimes S_1)', Y_k, X_k)$. Since $\neg\varphi'(S_0 \otimes S_1)$, we must have $(S_0 \otimes S_1)(1) \neq 1$. Hence $S_1(\langle k\rangle) = (S_0 \otimes S_1)(1) = 0$. This proves our claim.

By $\Delta^0_1$ comprehension let $Z \subseteq \mathbb{N}$ be the set of all $k$ such that $S_1(\langle k\rangle) = 1$. Then by the previous claim we have $\forall k\, ((\varphi_1(k) \to k \in Z) \wedge (\varphi_0(k) \to k \notin Z))$. This proves $\Sigma^1_1$ separation. Hence by theorem V.5.1 we have arithmetical transfinite recursion. This completes the proof of theorem V.8.7. □

EXERCISE V.8.8. Assume $\mathrm{WO}(X) \wedge \mathrm{WO}(Y)$. Let $G(X, Y)$ be the game of lemma V.8.6, in which the players play descending sequences through $X$ and $Y$ respectively. Show that player 1 has a winning strategy for $G(X, Y)$ if and only if $|X| \leq |Y|$. Formally,

$$\forall X\, \forall Y\, ((\mathrm{WO}(X) \wedge \mathrm{WO}(Y)) \to (\exists S_1\, \forall S_0\, \neg\varphi(S_0 \otimes S_1, X, Y) \leftrightarrow |X| \leq |Y|),$$

where $\varphi$ is as in lemma V.8.6.

**Notes for §V.8.** For an exposition of modern descriptive set theory based on the axiom of determinacy, see Moschovakis [191]. The fact that $\mathsf{ATR}_0$ proves $\Sigma^1_1$ choice (theorem V.8.3) is essentially due to Friedman [62, chapter II]. A version of theorem V.8.7 is in Steel [256]; this was one of the earliest results of Reverse Mathematics. Our proof of the reversal in theorem V.8.7 is new. Related results are in §§VI.5 and VI.7. See also Tanaka [263, 264].

## V.9. The $\Sigma^0_1$ and $\Delta^0_1$ Ramsey Theorems

In this section we shall discuss a certain "infinite exponent" generalization of Ramsey's theorem, namely the so-called *open Ramsey theorem*. We shall prove that the open Ramsey theorem is equivalent to $\mathsf{ATR}_0$ over $\mathsf{RCA}_0$.

The *Ramsey space* is the space $[\mathbb{N}]^{\mathbb{N}}$ of all total functions $f : \mathbb{N} \to \mathbb{N}$ such that $f$ is strictly increasing, i.e., $f(m) < f(n)$ for all $m, n \in \mathbb{N}$ such that $m < n$. For $f \in [\mathbb{N}]^{\mathbb{N}}$ and $m \in \mathbb{N}$ we write as usual

$$f[m] = \langle f(0), f(1), \ldots, f(m-1) \rangle.$$

Thus $f[m] \in [\mathbb{N}]^m$ (see definition III.7.3).

Given $f, g \in [\mathbb{N}]^{\mathbb{N}}$ we define $f \cdot g \in [\mathbb{N}]^{\mathbb{N}}$ by $(f \cdot g)(n) = f(g(n))$. A set $\mathcal{F} \subseteq [\mathbb{N}]^{\mathbb{N}}$ is called *Ramsey* if

$$\exists f\, (\forall g\, (f \cdot g \in \mathcal{F}) \vee \forall g\, (f \cdot g \notin \mathcal{F}));$$

here $f$ and $g$ range over points of $[\mathbb{N}]^{\mathbb{N}}$.

Remark. In the literature of Ramsey theory, it is usual to identify a strictly increasing function $f \in [\mathbb{N}]^{\mathbb{N}}$ with its range $\mathrm{rng}(f) \subseteq \mathbb{N}$. Thus the Ramsey space $[\mathbb{N}]^{\mathbb{N}}$ is identified with the space $[\mathbb{N}]^{\infty}$ of infinite subsets of $\mathbb{N}$. For $X \in [\mathbb{N}]^{\infty}$ one may write

$$[X]^{\infty} = \{ Y \in [\mathbb{N}]^{\infty} \colon Y \subseteq X \},$$

and then for $f \in [\mathbb{N}]^{\mathbb{N}}$ we have

$$[\mathrm{rng}(f)]^{\infty} = \{ \mathrm{rng}(f \cdot g) \colon g \in [\mathbb{N}]^{\mathbb{N}} \}.$$

With this notation, $\mathcal{F} \subseteq [\mathbb{N}]^{\infty}$ is said to be *Ramsey* if and only if there exists $X \in [\mathbb{N}]^{\infty}$ such that either $[X]^{\infty} \subseteq \mathcal{F}$ or $[X]^{\infty} \cap \mathcal{F} = \emptyset$. In our treatment of Ramsey theory here, we shall not make these identifications. However, the reader may find it useful to keep this viewpoint in mind.

The axiom of choice implies that there exist non-Ramsey subsets of $[\mathbb{N}]^{\mathbb{N}}$. However, it is also known that many subsets of $[\mathbb{N}]^{\mathbb{N}}$ are Ramsey. For example, the Galvin/Prikry theorem asserts that all Borel subsets of $[\mathbb{N}]^{\mathbb{N}}$ are Ramsey. See also Mathias [181] and Carlson/Simpson [33]. The purpose of the next definition is to formalize certain special cases of this principle as schemes in the language of second order arithmetic.

Definition V.9.1 ($\Sigma^0_1$-RT and $\Delta^0_1$-RT). The $\Sigma^0_1$ *Ramsey theorem*, denoted $\Sigma^0_1$-RT, is the scheme

$$\exists f\, (\forall g\, \varphi(f \cdot g) \vee \forall g\, \neg\varphi(f \cdot g))$$

where $\varphi$ is any $\Sigma^0_1$ formula. The $\Delta^0_1$ *Ramsey theorem*, denoted $\Delta^0_1$-RT, is the scheme

$$\forall h\, (\varphi(h) \leftrightarrow \psi(h)) \to \exists f\, (\forall g\, \varphi(f \cdot g) \vee \forall g\, \neg\varphi(f \cdot g))$$

where $\varphi$ and $\psi$ are $\Sigma^0_1$ and $\Pi^0_1$ respectively. Here $f$, $g$, and $h$ range over $[\mathbb{N}]^{\mathbb{N}}$. The $\Sigma^i_k$ and $\Delta^i_k$ *Ramsey theorems*, $i < 2$, $1 \leq k \leq \infty$, denoted $\Sigma^i_k$-RT and $\Delta^i_k$-RT respectively, are defined similarly.

Note that $\Sigma^0_\infty$-RT and $\Sigma^1_\infty$-RT are not expressible as single sentences of $L_2$. Rather, they are schemes. (We may call them *Ramsey schemes*.) However, for $k < \infty$, each of $\Sigma^i_k$-RT and $\Delta^i_k$-RT for $i \in \{0,1\}$ may be expressed by means of codes as a single sentence of $L_2$. The appropriate codes for the $\Sigma^0_1$ case are given by the following definition.

DEFINITION V.9.2 (open sets in $[\mathbb{N}]^\mathbb{N}$). Let $[\mathbb{N}]^{<\mathbb{N}} = \bigcup_{m\in\mathbb{N}}[\mathbb{N}]^m =$ the set of all (codes for) strictly increasing finite sequences of natural numbers. (A sequence $\sigma \in \mathbb{N}^{<\mathbb{N}} = \mathrm{Seq}$ is said to be *strictly increasing* if $\sigma(i) < \sigma(j)$ for all $i < j < \mathrm{lh}(\sigma)$.) In $\mathsf{RCA}_0$, a *code for an open subset of* $[\mathbb{N}]^\mathbb{N}$ is defined to be a subset $P$ of $[\mathbb{N}]^{<\mathbb{N}}$; we then write $f \in P$ to mean that $f \in [\mathbb{N}]^\mathbb{N}$ and $\exists m\,(f[m] \in P)$. In this sense we may write $P \subseteq [\mathbb{N}]^\mathbb{N}$.

Note that, by our formalized Kleene normal form theorem II.2.7, $P \subseteq [\mathbb{N}]^\mathbb{N}$ is open if and only if it is $\Sigma^0_1$ definable. This is provable in $\mathsf{RCA}_0$.

DEFINITION V.9.3 (open Ramsey theorem). The *open Ramsey theorem* is defined in $\mathsf{RCA}_0$ to be the statement that for all (codes for) open sets $P \subseteq [\mathbb{N}]^\mathbb{N}$ there exists $f$ such that $\forall g(f \cdot g \in P) \vee \forall g(f \cdot g \notin P)$. The *clopen Ramsey theorem* is defined in $\mathsf{RCA}_0$ to be the statement that for all (codes for) open sets $P, Q \subseteq [\mathbb{N}]^\mathbb{N}$, if $\forall h\,(h \in P \leftrightarrow h \notin Q)$ then

$$\exists f\,(\forall g\,(f \cdot g \in P) \vee \forall g\,(f \cdot g \notin P)).$$

Here $f$, $g$ and $h$ range over $[\mathbb{N}]^\mathbb{N}$. Clearly ($\Sigma^0_1$-RT $\leftrightarrow$ open Ramsey theorem) and ($\Delta^0_1$-RT $\leftrightarrow$ clopen Ramsey theorem) are provable in $\mathsf{RCA}_0$.

LEMMA V.9.4. *The open Ramsey theorem is provable in* $\mathsf{ATR}_0$.

PROOF. We reason in $\mathsf{ATR}_0$. Let $P$ be a code for an open set in $[\mathbb{N}]^\mathbb{N}$ such that for all $f \in [\mathbb{N}]^\mathbb{N}$ there exists $g \in [\mathbb{N}]^\mathbb{N}$ such that $f \cdot g \in P$. We shall prove that there exists $f \in [\mathbb{N}]^\mathbb{N}$ such that $f \cdot g \in P$ for all $g \in [\mathbb{N}]^\mathbb{N}$.

Form the tree $T = \{\sigma \in [\mathbb{N}]^{<\mathbb{N}}$: no subsequence of $\sigma$ is in $P\}$. Our assumption $\forall f\,\exists g\; f \cdot g \in P$ implies that $T$ is well founded, i.e., $T$ has no infinite path. Hence the Kleene/Brouwer ordering $\mathrm{KB}(T)$ is a well ordering.

For infinite sets $U, V \subseteq \mathbb{N}$, let us write $U \subseteq^\infty V$ to mean that $U$ is almost included in $V$, i.e., $U \setminus V$ is finite.

We shall classify each $\sigma \in [\mathbb{N}]^{<\mathbb{N}}$ as either *good* or *bad*. For $\sigma \notin T$, let $\sigma'$ be the smallest initial segment of $\sigma$ such that $\sigma' \notin T$, and classify $\sigma$ as good if $\sigma' \in P$, bad if $\sigma' \notin P$. For $\sigma \in T$, we shall use arithmetical transfinite recursion along $\mathrm{KB}(T)$ to classify $\sigma$ as good or bad and simultaneously to define an infinite set $U_\sigma \subseteq \mathbb{N}$ with the following properties:

1. if $\tau <_{\mathrm{KB}(T)} \sigma$ then $U_\sigma \subseteq^\infty U_\tau$;
2. if $\sigma$ is good then $\sigma^\frown\langle n\rangle$ is good for all $n \in U_\sigma$;
3. if $\sigma$ is bad then $\sigma^\frown\langle n\rangle$ is bad for all $n \in U_\sigma$.

Given $\sigma \in T$, assume inductively that $U_\tau$ has been defined and that $\tau$ has been classified as good or bad, for each $\tau <_{\mathrm{KB}(T)} \sigma$. By a straightforward

diagonal construction, define an infinite set $V$ such that $V \subseteq^\infty U_\tau$ for all $\tau <_{\mathrm{KB}(T)} \sigma$. If there are infinitely many $n \in V$ such that $\sigma^\frown\langle n\rangle$ is good, classify $\sigma$ as good and define $U_\sigma = \{n \in V : \sigma^\frown\langle n\rangle \text{ is good}\}$. Otherwise classify $\sigma$ as bad and define $U_\sigma = \{n \in V : \sigma^\frown\langle n\rangle \text{ is bad}\}$. This transfinite recursion continues until the empty sequence $\langle\rangle$ has been classified as good or bad and $U_{\langle\rangle}$ has been defined.

We claim that $\langle\rangle$ is good. Suppose not, i.e., $\langle\rangle$ is bad. Define an increasing sequence of integers $k_0 < k_1 < \cdots < k_n < \cdots$, $n \in \mathbb{N}$. Begin by defining $k_0$ to be the least element of $U_{\langle\rangle}$. If $k_0 < \cdots < k_n$ have been defined, put $W_n = \bigcap\{U_\sigma : \sigma \text{ is a subsequence of } \langle k_0, \ldots, k_n\rangle\}$ and let $k_{n+1}$ be the least $m \in W_n$ such that $m > k_n$. Since $\langle\rangle$ is bad, it is clear by induction on $n$ that every subsequence of $\langle k_0, \ldots, k_n\rangle$ is bad, for all $n \in \mathbb{N}$. Now define $f \in [\mathbb{N}]^\mathbb{N}$ by putting $f(n) = k_n$, for all $n$. Then $f \cdot g \notin P$ for all $g \in [\mathbb{N}]^\mathbb{N}$, a contradiction. This proves our claim.

Since $\langle\rangle$ is good, the same construction can be used to obtain an increasing sequence $k_0 < k_1 < \cdots < k_n < \cdots$ every finite subsequence of which is good. Again define $f \in [\mathbb{N}]^\mathbb{N}$ by putting $f(n) = k_n$ for all $n$. Since $T$ is well founded, for every $g \in [\mathbb{N}]^\mathbb{N}$ there is a least $m$ such that $(f \cdot g)[m] \notin T$. Since $(f \cdot g)[m]$ is good, we have $f \cdot g \in P$. This completes the proof of lemma V.9.4. □

The rest of this section is devoted to the reversal of lemma V.9.4. We shall in fact show that the clopen Ramsey theorem implies arithmetical transfinite recursion. We begin with:

LEMMA V.9.5. *It is provable in* $\mathsf{RCA}_0$ *that the clopen Ramsey theorem implies arithmetical comprehension.*

PROOF. From §III.7 we know that arithmetical comprehension is equivalent over $\mathsf{RCA}_0$ to $\mathrm{RT}(3)$, i.e., Ramsey's theorem for exponent 3. We shall now prove within $\mathsf{RCA}_0$ that the clopen Ramsey theorem implies $\mathrm{RT}(3)$.

Given a coloring of 3-tuples $F : [\mathbb{N}]^3 \to \{0, 1\}$, define for $i = 0, 1$

$$P_i = \{\sigma \in [\mathbb{N}]^{<\mathbb{N}} : \mathrm{lh}(\sigma) = 3 \wedge F(\sigma) = i\}.$$

Thus $P_0$ and $P_1$ are subsets of $[\mathbb{N}]^{<\mathbb{N}}$, and for all $h \in [\mathbb{N}]^\mathbb{N}$ we have $h \in P_i \leftrightarrow F(h[3]) = i$, hence $h \in P_0 \leftrightarrow h \notin P_1$. Thus, by the clopen Ramsey theorem, there exist $f \in [\mathbb{N}]^\mathbb{N}$ and $i \in \{0, 1\}$ such that $f \cdot g \in P_i$ for all $g \in [\mathbb{N}]^\mathbb{N}$. By $\Delta^0_1$ comprehension there exists $X = \mathrm{rng}(f) = \{n : \exists m \leq n(f(m) = n)\}$, since $f$ is strictly increasing. Clearly $X \subseteq \mathbb{N}$ is infinite and $[X]^3 \subseteq P_i$, i.e., $F(\sigma) = i$ for all $\sigma \in [X]^3$. This proves $\mathrm{RT}(3)$. Hence by lemma III.7.5 we have arithmetical comprehension. □

LEMMA V.9.6 (clopen Ramsey reversal). *It is provable in* $\mathsf{RCA}_0$ *that the clopen Ramsey theorem implies arithmetical transfinite recursion.*

PROOF. Assume the clopen Ramsey theorem. By lemma V.9.5 we have arithmetical comprehension. We wish to prove arithmetical transfinite

recursion. Instead of proving this directly, we shall prove the equivalent $\Sigma^1_1$ separation principle V.5.1.2. Reasoning in $\mathsf{ACA}_0$, assume that $\neg\exists k\,(\varphi_1(k) \wedge \varphi_0(k))$ where $\varphi_1(k)$ and $\varphi_0(k)$ are $\Sigma^1_1$. We seek a set $Z \subseteq \mathbb{N}$ such that $\forall k\,((\varphi_1(k) \to k \in Z) \wedge (\varphi_0(k) \to k \notin Z))$. By theorem V.1.7′ there exist sequences of trees $\langle T^i_k : k \in \mathbb{N}\rangle$, $i \in \{0,1\}$, such that $\forall k\,(\varphi_i(k) \leftrightarrow T^i_k$ has a path). By assumption we have $\forall k\,(T^1_k$ and $T^0_k$ do not both have a path).

Given any tree $T \subseteq \mathrm{Seq}$, let us say that $f \in [\mathbb{N}]^{\mathbb{N}}$ *majorizes* $T$ if there exists $g : \mathbb{N} \to \mathbb{N}$ such that $g$ is a path through $T$ and $\forall m\,(g(m) \leq f(m))$. Let us say that $\sigma \in [\mathbb{N}]^{<\mathbb{N}}$ *majorizes* $T$ if there exists $\tau \in T$ such that $\mathrm{lh}(\tau) = \mathrm{lh}(\sigma)$ and $\forall j < \mathrm{lh}(\sigma)\,(\tau(j) \leq \sigma(j))$. By König's lemma (theorem III.7.2) it follows that $f \in [\mathbb{N}]^{\mathbb{N}}$ majorizes $T$ if and only if $\forall m\,(f[m]$ majorizes $T)$. Applying this to the $T^i_k$'s from the previous paragraph, we have that $\forall k\,\exists m\,(f[m]$ does not majorize both $T^1_k$ and $T^0_k)$.

Given $h \in [\mathbb{N}]^{\mathbb{N}}$ define $m_h =$ the least $m > 0$ such that for all $k \leq h(0)$, $\langle h(1), h(2), \ldots, h(m)\rangle$ does not majorize both $T^1_k$ and $T^0_k$. Then define $n_h =$ the least $n > m_h$ such that for all $k \leq h(0)$, $\langle h(m_h+1), h(m_h+2), \ldots, h(n)\rangle$ does not majorize both $T^1_k$ and $T^0_k$. Let $P$ and $Q$ be (codes for) open subsets of $[\mathbb{N}]^{\mathbb{N}}$ such that for all $h \in [\mathbb{N}]^{\mathbb{N}}$, $h \in P \leftrightarrow h \notin Q$, and $h \in P$ if and only if $\forall k \leq h(0)\,(\langle h(1), h(2), \ldots, h(m_h)\rangle$ majorizes $T^1_k \leftrightarrow \langle h(m_h+1), h(m_h+2), \ldots, h(n_h)\rangle$ majorizes $T^1_k)$.

We claim that for all $f \in [\mathbb{N}]^{\mathbb{N}}$ there exists $g \in [\mathbb{N}]^{\mathbb{N}}$ such that $f \cdot g \in P$. To see this, let $f \in [\mathbb{N}]^{\mathbb{N}}$ be given. Define $m_0 < m_1 < \cdots < m_i < \cdots$ by $m_0 = 0$, $m_{i+1} =$ least $n > m_i$ such that $\forall k \leq f(0)(\langle f(m_i+1), f(m_i+2), \ldots, f(n)\rangle$ does not majorize both $T^1_k$ and $T^0_k)$. By the pigeonhole principle there exist $i$ and $j$ such that $i < j$ and $\forall k \leq f(0)(\langle f(m_i+1), \ldots, f(m_{i+1})\rangle$ majorizes $T^1_k \leftrightarrow \langle f(m_j+1), \ldots, f(m_{j+1})\rangle$ majorizes $T^1_k)$. Let $g \in [\mathbb{N}]^{\mathbb{N}}$ be such that $g(0) = 0$, $g(1) = m_i + 1$, $\ldots$, $g(m_{i+1} - m_i) = m_{i+1}$, $g(m_{i+1} - m_i + 1) = m_j + 1$, $\ldots$, $g(m_{i+1} - m_i + m_{j+1} - m_j) = m_{j+1}$. Putting $h = f \cdot g$ we see that $\langle h(1), \ldots, h(m_h)\rangle = \langle f(m_i+1), \ldots, f(m_{i+1})\rangle$ and $\langle h(m_h+1), \ldots, h(n_h)\rangle = \langle f(m_j+1), \ldots, f(m_{j+1})\rangle$. It follows that $f \cdot g = h \in P$. This proves our claim.

From the above claim plus the clopen Ramsey theorem, it follows that there exists $f \in [\mathbb{N}]^{\mathbb{N}}$ such that $f \cdot g \in P$ for all $g \in [\mathbb{N}]^{\mathbb{N}}$. For each $k \in \mathbb{N}$ define $f_k \in [\mathbb{N}]^{\mathbb{N}}$ by $f_k(m) = f(k+m)$. Using arithmetical (actually $\Delta^0_1$) comprehension, let $Z$ be the set of all $k$ such that $\langle f_k(1), f_k(2), \ldots, f_k(m_{f_k})\rangle$ majorizes $T^1_k$. We claim that $\forall k((\varphi_1(k) \to k \in Z) \wedge (\varphi_0(k) \to k \notin Z))$. Suppose first that $\varphi_1(k)$ holds, i.e., $T^1_k$ has a path, but $k \notin Z$. Let $g \in [\mathbb{N}]^N$ be such that $g(0) = k$, $g(1) = k+1, \ldots, g(m_{f_k}) = k + m_{f_k}$, and $\langle g(m_{f_k}+1), g(m_{f_k}+2), \ldots\rangle$ majorizes $T^1_k$. Putting $h = f \cdot g$ we see that $k \leq f(k) = h(0)$ and $\langle h(1), \ldots, h(m_h)\rangle = \langle f_k(1), \ldots, f_k(m_{f_k})\rangle$ does not majorize $T^1_k$, while $\langle h(m_h+1), \ldots, h(n_h)\rangle = \langle f(g(m_{f_k}+1)), f(g(m_{f_k}+2)), \ldots, f(g(n_h))\rangle$

does majorize $T^1_k$. Thus $f \cdot g = h \notin P$, a contradiction. This shows that $\forall k(\varphi_1(k) \to k \in Z)$. A similar argument shows that $\forall k(\varphi_0(k) \to k \notin Z)$. This completes the proof of lemma V.9.6. □

Summarizing, we have:

Theorem V.9.7. *The following are pairwise equivalent over* $\mathsf{RCA}_0$:

1. $\mathsf{ATR}_0$;
2. *the open Ramsey theorem*, $\Sigma^0_1$-RT;
3. *the clopen Ramsey theorem*, $\Delta^0_1$-RT.

Proof. This is immediate from lemmas V.9.4 and V.9.6. □

**Notes for §V.9.** Questions concerning effectivity of the open and clopen Ramsey theorems have been considered by Simpson [232], Mansfield [170], Clote [37], and Solovay [252]. The results of this section were first proved in Friedman/McAloon/Simpson [76] using formalized hyperarithmetical theory, pseudohierarchies, and inner models. The greatly simplified proofs of lemmas V.9.4 and V.9.6 presented here are due to Avigad [9] and Jockusch (personal communication), respectively. Some refinements of theorem V.9.7 are in Friedman/McAloon/Simpson [76, appendix] and in Simpson [235]. Other results related to theorem V.9.7 are in §§III.7, VI.6, VI.7.

## V.10. Conclusions

In this chapter we have seen that many ordinary mathematical theorems are logically equivalent to $\mathsf{ATR}_0$. Among these are: Lusin's separation theorem V.3.9, the Borel domain theorem V.3.11, the perfect set theorem V.4.3, comparability of countable well orderings (§V.6), the existence of Ulm resolutions (§V.7), open and clopen determinacy (§V.8), and the open and clopen Ramsey theorems (§V.9). In order to prove these equivalences, several interesting techniques have been developed. Prominent among the proof techniques are the method of pseudohierarchies (§V.4) and a technique of doing reversals via $\Sigma^1_1$ separation (theorem V.5.1) and unique paths (theorem V.5.2).

In §V.8 we obtained the following interesting result: $\mathsf{ATR}_0$ proves $\Sigma^1_1$ choice. This may be compared to the related results obtained in §§VIII.4–VIII.5.

Remark V.10.1 (the method of inner models). One important $\mathsf{ATR}_0$ technique which has not appeared in this chapter is the method of inner models, where countable coded $\omega$-models of $\Sigma^1_1$-$\mathsf{AC}_0$ (see §VIII.4) are used to prove mathematical theorems in $\mathsf{ATR}_0$. A rather difficult application of this technique will appear in our treatment of Silver's theorem (lemma VI.3.1), below. See also Marcone [172]. Other applications

are in the original proof of the open Ramsey theorem in $\mathsf{ATR}_0$ (Friedman/McAloon/Simpson [76]), and in the proof of the countable König duality theorem in $\mathsf{ATR}_0$ (Simpson [247]). A related inner model technique is also useful for proving mathematical theorems in $\Pi^1_1$-$\mathsf{CA}_0$; see §§VI.5–VI.6.

Chapter VI

# $\Pi^1_1$ COMPREHENSION

In §I.5 we introduced the formal system $\Pi^1_1$-$\mathsf{CA}_0$ of $\Pi^1_1$ comprehension. In §I.6 we explained how $\Pi^1_1$-$\mathsf{CA}_0$ is much stronger than $\mathsf{ACA}_0$ from the viewpoint of mathematical practice. In §I.9 we saw that $\Pi^1_1$-$\mathsf{CA}_0$ is one of five basic subsystems of $\mathsf{Z}_2$ which are important for Reverse Mathematics.

The purpose of this chapter is to present some details of results which were merely outlined in §§I.6 and I.9. Specifically, we discuss mathematics and Reverse Mathematics for $\Pi^1_1$-$\mathsf{CA}_0$ and stronger systems. Models of these systems will be considered later, in §§VII.1, VII.5–VII.7, VIII.6, and IX.4.

## VI.1. Perfect Kernels

In this section we complete the discussion of perfect trees which was begun in §§V.4 and V.5. We also prove that a certain well known theorem about the structure of closed sets, the Cantor/Bendixson theorem, is equivalent to $\Pi^1_1$ comprehension.

The following lemma is useful in showing that various mathematical statements are equivalent to $\Pi^1_1$ comprehension. (Compare theorem V.5.2.)

LEMMA VI.1.1 ($\Pi^1_1$-$\mathsf{CA}_0$ and paths through trees). *The following are equivalent over* $\mathsf{RCA}_0$.

1. $\Pi^1_1$ *comprehension*.
2. *For any sequence of trees* $\langle T_k : k \in \mathbb{N} \rangle$, $T_k \subseteq \mathbb{N}^{<\mathbb{N}}$, *there exists a set* $X$ *such that* $\forall k\, (k \in X \leftrightarrow T_k$ *has a path*$)$.

PROOF. Obviously $\Pi^1_1$-$\mathsf{CA}_0$ proves statement 2.

Suppose now that statement 2 holds. We want to prove $\Pi^1_1$ comprehension. We first prove arithmetical comprehension. For this, it suffices to show that every function $g : \mathbb{N} \to \mathbb{N}$ has a range (see theorem III.1.3). Given $g$, use $\Delta^0_1$ comprehension to get the sequence of trees $\langle T_k : k \in \mathbb{N} \rangle$ where $\tau \in T_k$ if and only if $(\forall m < \mathrm{lh}(\tau))\, (g(m) \neq k)$. Clearly $T_k$ has a

path if and only if $\neg\exists m\,(g(m) = k)$. Hence VI.1.1.2 implies the existence of $\mathrm{rng}(g)$. Thus we have arithmetical comprehension.

Now let $\varphi(k)$ be a $\Sigma^1_1$ formula. We want to prove that $\{k : \varphi(k)\}$ exists. Using arithmetical comprehension, our formal version of the Kleene normal form theorem (lemma V.1.4) gives us an arithmetical formula $\theta(k, \tau)$ such that

$$\forall k\,(\varphi(k) \leftrightarrow \exists f\,\forall m\,\theta(k, f[m])).$$

By arithmetical comprehension, let $\langle T_k : k \in \mathbb{N}\rangle$ be the sequence of trees defined by putting $\tau \in T_k$ if and only if $(\forall m \leq \mathrm{lh}(\tau))\,\theta(k, \tau[m])$. Then clearly $\varphi(k)$ holds if and only if $T_k$ has a path. Thus VI.1.1.2 implies the existence of a set $X$ such that $\forall k\,(k \in X \leftrightarrow \varphi(k))$. This proves $\Sigma^1_1$ comprehension, which is clearly equivalent to $\Pi^1_1$ comprehension.

The proof of lemma VI.1.1 is complete. □

We now consider what might be called a Cantor/Bendixson theorem for trees.

Definition VI.1.2 (perfect kernel of a tree). Let $T \subseteq \mathbb{N}^{<\mathbb{N}}$ be a tree. The *perfect kernel* of $T$ is defined in $\mathsf{RCA}_0$ to be the union of all of the perfect subtrees of $T$, provided this union exists. Note that the perfect kernel of $T$, if it exists, is a perfect tree (definition V.4.1), namely the unique largest perfect subtree of $T$.

Theorem VI.1.3 ($\Pi^1_1$-$\mathsf{CA}_0$). *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\Pi^1_1$ *comprehension*.
2. *For any tree* $T \subseteq \mathbb{N}^{<\mathbb{N}}$, *the perfect kernel of* $T$ *exists.*
3. *Same as* 2 *for trees* $T \subseteq 2^{<\mathbb{N}}$.
4. *For any tree* $T \subseteq \mathbb{N}^{<\mathbb{N}}$, *there is a perfect subtree* $P \subseteq T$ *such that the set of paths through* $T$ *which are not paths through* $P$ *is countable.*
5. *Same as* 4 *for trees* $T \subseteq 2^{<\mathbb{N}}$.

Proof. We begin by proving $1 \to 2$ and $1 \to 4$. Reasoning in $\Pi^1_1$-$\mathsf{CA}_0$, let $T$ be a subtree of $\mathbb{N}^{<\mathbb{N}}$. For each $\sigma \in \mathbb{N}^{<\mathbb{N}}$, put $T_\sigma = \{\tau \in T : \tau \subseteq \sigma \vee \sigma \subseteq \tau\}$. By $\Pi^1_1$ comprehension, let $P$ be the set of all $\sigma \in T$ such that $T_\sigma$ has a nonempty perfect subtree. Clearly $P$ is the perfect kernel of $T$. This proves 2. By recursive comprehension, form the tree

$$T' = T/P = \{\langle\sigma\rangle^\frown\tau : \sigma \in T \setminus P \wedge \tau \in T_\sigma\}.$$

Clearly $T'$ has no nonempty perfect subtree. Hence, by theorem V.5.5.4, $T'$ has only countably many paths, i.e., there exists $\langle f_n : n \in \mathbb{N}\rangle$ such that $\forall f$ (if $f$ is a path through $T'$ then $\exists n\,(f = f_n)$). It follows that $\forall f$ (if $f$ is a path through $T$ then either $f$ is a path through $P$ or $\exists n(f = f'_n)$), where $f'_n(m) = f_n(m + 1)$. We have now proved $1 \to 2$ and $1 \to 4$.

Obviously $2 \to 3$ and $4 \to 5$. Reasoning in $\mathsf{RCA}_0$, it remains to prove that either 3 or 5 implies $\Pi^1_1$ comprehension. We shall use lemma

VI.1.1. Let $\langle T_k : k \in \mathbb{N}\rangle$ be a sequence of trees, $T_k \subseteq \mathbb{N}^{<\mathbb{N}}$. By recursive comprehension, form the sequence of trees $\langle T'_k : k \in \mathbb{N}\rangle$ where $T'_k$ consists of all sequences of the form $\langle (m_0, n_0), \ldots, (m_{j-1}, n_{j-1})\rangle$ such that $\langle m_0, \ldots, m_{j-1}\rangle \in T_k$. Thus $T_k$ has a path if and only if $T'_k$ has a nonempty perfect subtree. Now put

$$T = \{\langle\rangle\} \cup \{\langle k\rangle^\frown \tau : k \in \mathbb{N} \wedge \tau \in T'_k\} \subseteq \mathbb{N}^{<\mathbb{N}}$$

and form the associated tree $T^* \subseteq 2^{<\mathbb{N}}$ as in the proof of lemma V.5.6. Let $P^* \subseteq T^*$ be a perfect tree as in 3 or 5. By recursive comprehension, let $X$ be the set of all $k$ such that

$$\langle \underbrace{0, \ldots, 0}_{k}, 1\rangle \in P^*.$$

Clearly $T_k$ has a path if and only if $k \in X$. By lemma VI.1.1, this proves $\Pi^1_1$ comprehension. The proof of theorem VI.1.3 is complete. □

We now turn to our discussion of closed sets.

DEFINITION VI.1.4 (perfect sets). Within $\mathsf{RCA}_0$, we define a closed set $C$ in a complete separable metric space to be *perfect* if it has no isolated points, i.e., for any point $x \in C$ and any $\epsilon > 0$ there exists $y \in C$ such that $0 < d(x, y) < \epsilon$.

The relationship between closed sets in $\mathbb{N}^{\mathbb{N}}$ and trees in $\mathbb{N}^{<\mathbb{N}}$ is given by the following lemma.

LEMMA VI.1.5. *The following is provable in* $\mathsf{RCA}_0$. *For any closed set* $C \subseteq \mathbb{N}^{\mathbb{N}}$, *there exists a tree* $T \subseteq \mathbb{N}^{<\mathbb{N}}$ *such that*

$$\forall f\ (f \in C \leftrightarrow f \text{ is a path through } T). \tag{17}$$

*Conversely, for any tree* $T \subseteq \mathbb{N}^{<\mathbb{N}}$, *there exists a closed set* $C = [T] \subseteq \mathbb{N}^{\mathbb{N}}$ *such that* (17) *holds. If* $T$ *is a perfect tree, then* $C$ *is a perfect set*.

PROOF. The formula $f \in C$ is $\Pi^0_1$ (using the code of $C$ as a parameter). Hence by the normal form theorem II.2.7 for $\Pi^0_1$ formulas, we can find a $\Sigma^0_0$ formula $\theta(\tau)$ such that $\forall f\,(f \in C \leftrightarrow \forall m\, \theta(f[m]))$. Let $T$ be the tree of all $\tau \in \mathbb{N}^{<\mathbb{N}}$ such that $(\forall m \le \mathrm{lh}(\tau))\, \theta(\tau[m])$. Then clearly (17) holds. Conversely, given a tree $T$, note that the formula "$f$ is a path through $T$" is $\Pi^0_1$. Hence by lemma II.5.7 there is a closed set $C$ such that (17) holds. If $T$ is perfect, then for all paths $f$ through $T$ we have $\forall n\, \exists g$ ($g$ is a path through $T$ and $g \neq f$ and $g[n] = f[n]$). Hence the closed set $C$ corresponding to $T$ is perfect. This proves the lemma. □

THEOREM VI.1.6 (Cantor/Bendixson and $\Pi^1_1$-$\mathsf{CA}_0$). *The following are equivalent over* $\mathsf{ACA}_0$.

1. $\Pi^1_1$ *comprehension*.
2. *Every closed set in* $\mathbb{N}^{\mathbb{N}}$ *is the union of a perfect closed set and a countable set*. (This is the Cantor/Bendixson theorem for $\mathbb{N}^{\mathbb{N}}$.)

3. *Same as* 2 *for closed sets in* $2^{\mathbb{N}}$. (This is the Cantor/Bendixson theorem for $2^{\mathbb{N}}$.)

PROOF. The implication $1 \to 2$ is immediate from theorem VI.1.3 and lemma VI.1.5. Moreover $2 \to 3$ is trivial. It remains to prove $3 \to 1$. Assume 3. Instead of proving 1 we shall prove the equivalent assertion VI.1.3.5. Let $T$ be a subtree of $2^{<\mathbb{N}}$. By lemma VI.1.5 let $C = [T]$, i.e., $C$ is the closed set in $2^{\mathbb{N}}$ whose points are the paths through $T$. By our assumption VI.1.6.3, let $C_1$ be a perfect closed subset of $C$ such that $C \setminus C_1$ is countable. By lemma VI.1.5, let $T_1$ be a tree whose paths are just the elements of $C_1$. By weak König's lemma plus arithmetical comprehension, there exists $\widehat{T_1}$ consisting of all $\sigma \in T_1$ such that $\exists f\,(f[\mathrm{lh}(\sigma)] = \sigma \wedge \forall m\,(f[m] \in T_1))$, i.e., ($\exists$ infinitely many $\tau \in T_1$ such that $\tau \supseteq \sigma$). Then clearly $\widehat{T_1}$ is a perfect subtree of $T_1$ and $[\widehat{T_1}] = [T_1] = C_1$, i.e., $\forall f\,(f \in C_1 \leftrightarrow f$ is a path through $\widehat{T_1})$. This proves VI.1.3.5. Hence by theorem VI.1.3 we have $\Pi^1_1$ comprehension. □

EXERCISE VI.1.7. Generalize theorem VI.1.6 to complete separable metric spaces. In other words, show that $\Pi^1_1$ comprehension is equivalent over $\mathsf{ACA}_0$ to the assertion that every closed set $C$ in a complete separable metric space can be written as $C = P \cup S$ where $P$ is a perfect closed set and $S$ is countable. (This assertion is known as the *Cantor/Bendixson theorem*, and $P$ is known as the *perfect kernel* of $C$.)

EXERCISE VI.1.8. For $\sigma, \tau \in \mathbb{N}^{<\mathbb{N}}$ say that $\sigma$ *majorizes* $\tau$ if $\mathrm{lh}(\sigma) = \mathrm{lh}(\tau)$ and $(\forall i < \mathrm{lh}(\sigma))\,(\sigma(i) \geq \tau(i))$. Given a tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$, define

$$T^+ = \{\sigma \in \mathbb{N}^{<\mathbb{N}} \colon \exists \tau\,(\tau \in T \wedge \sigma \text{ majorizes } \tau)\}.$$

Prove:

1. $T^+$ is a tree; $T^+ \supseteq T$; $T^{++} = T^+$.
2. $T$ is well founded if and only if $T^+$ is well founded. (Hint: Use bounded König's lemma.)
3. If $T$ is well founded, then $\mathrm{o}(T) = \mathrm{o}(T^+)$. Here $\mathrm{o}(T)$ denotes the ordinal height of $T$.

EXERCISE VI.1.9. A tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ is said to be *smooth* if $T^+ = T$. Show that lemma VI.1.1 holds with "tree" replaced by "smooth tree".

**Notes for §VI.1.** The equivalence of $\Pi^1_1$ comprehension with VI.1.3.2 was announced by Friedman [69]. Exercise VI.1.7 is related to a result of Kreisel [149], who used hyperarithmetical theory to refute a certain predicative analog of the Cantor/Bendixson theorem. Exercises VI.1.8 and VI.1.9 are from Marcone [173, 174]; see also Humphreys/Simpson [127].

## VI.2. Coanalytic Uniformization

In this section we continue our exploration of classical descriptive set theory as formalized within subsystems of second order arithmetic. We show that one of the most famous theorems of classical descriptive set theory, Kondo's theorem, is equivalent to $\Pi^1_1$ comprehension. The equivalence is proved in $\mathsf{ATR}_0$.

We begin with the following lemma, which is a formal version of the $\Pi^1_1$ *uniformization principle*.

Lemma VI.2.1 ($\Pi^1_1$ uniformization in $\Pi^1_1$-$\mathsf{CA}_0$). *Let $\psi(X)$ be a $\Pi^1_1$ formula with a distinguished free set variable $X$. Then we can find a $\Pi^1_1$ formula $\widehat{\psi}(X)$ such that $\Pi^1_1$-$\mathsf{CA}_0$ proves*

(1) $\forall X\,(\widehat{\psi}(X) \to \psi(X))$,
(2) $\forall Y\,(\psi(Y) \to \exists X\,\widehat{\psi}(X))$,
(3) $\forall X\,\forall Y\,((\widehat{\psi}(X) \wedge \widehat{\psi}(Y)) \to X = Y)$.

Proof. The proof will be based on the analysis of $\Pi^1_1$ formulas given in §V.1, in terms of analytic codes and the Kleene/Brouwer ordering.

By lemma V.1.8, we have an analytic code $A$ such that

$$\forall X(\psi(X) \leftrightarrow \mathrm{WO}(\mathrm{KB}(\mathrm{T}_A(X)))).$$

Let us write $L(X) = \mathrm{KB}(\mathrm{T}_A(X))$. Then we have $\forall X\ \mathrm{LO}(L(X))$ and

$$\forall X(\psi(X) \leftrightarrow \mathrm{WO}(L(X))).$$

For each $k \in \mathbb{N}$ put

$$L_k(X) = \{(i,j)\colon i \leq_{L(X)} j <_{L(X)} k\}.$$

Thus $L_k(X)$ is the initial segment of $L(X)$ determined by $k$. (If $k \notin \mathrm{field}(L(X))$ then $L_k(X)$ is defined to be all of $L(X)$.)

Reasoning in $\Pi^1_1$-$\mathsf{CA}_0$, assume that there exists $X$ such that $\psi(X)$ holds, i.e., $\mathrm{WO}(L(X))$. We claim that there exists $X_0$ such that $\mathrm{WO}(L(X_0))$ holds and $|L(X_0)|$ is minimal, i.e.,

$$\forall X\,(\mathrm{WO}(L(X)) \to |L(X)| \geq |L(X_0)|).$$

To see this, start with any $Y$ such that $\psi(Y)$ holds. If

$$\forall X\,(\mathrm{WO}(L(X)) \to |L(X)| \geq |L(Y)|)$$

holds, then we may take $X_0 = Y$ and our claim is proved. If not, put

$$K = \{k\colon k \in \mathrm{field}(L(Y)) \wedge \exists X\,|L(X)| = |L_k(Y)|\}.$$

Here $K$ exists by $\Sigma^1_1$ comprehension, with $Y$ as a parameter. By assumption, $K \neq \emptyset$. Let $k_0$ be the $\leq_{L(Y)}$-least element of $K$. Let $X_0$ be such that $|L(X_0)| = |L_{k_0}(Y)|$. Clearly this proves the claim.

Fix $X_0$ as in the above claim, and let $G$ be the set of all $\sigma \in \mathrm{Seq}$ of the form $\langle(\xi_0, m_0), \ldots, (\xi_{k-1}, m_{k-1})\rangle$ such that

(4) $\exists X\,(|L(X)| = |L(X_0)| \wedge (\forall i < k)\,(X(i) = \xi_i \wedge |L_i(X)| = |L_{m_i}(X_0)|))$.

Here $G$ exists by $\Sigma^1_1$ comprehension, with $X_0$ as a parameter. ($G$ is in fact an analytic code.) Clearly the empty sequence $\langle\rangle$ belongs to $G$.

We claim that for all $\sigma \in G$ there exist $\xi \in \{0,1\}$ and $m \in \mathbb{N}$ such that $\sigma^\frown\langle(\xi, m)\rangle$ belongs to $G$. To see this, let $\sigma = \langle(\xi_0, m_0), \ldots, (\xi_{k-1}, m_{k-1})\rangle \in G$ and pick any $X$ as in (4). Put $\xi = X(k)$ and, by comparability of well orderings, $m =$ the unique $m$ such that $|L_k(X)| = |L_m(X_0)|$. (If $k \notin \text{field}(L(X))$ we may take any $m \notin \text{field}(L(X_0))$.) Clearly $\sigma^\frown\langle(\xi, m)\rangle \in G$. This proves the claim.

Now define $\sigma_k \in G, k \in \mathbb{N}$, by putting $\sigma_0 = \langle\rangle$ and $\sigma_{k+1} = \sigma_k{}^\frown\langle(\xi_k, m_k)\rangle$, where $\xi_k$ is the least $\xi$ such that $\exists m(\sigma_k{}^\frown\langle(\xi, m)\rangle \in G)$, and $m_k$ is the $<_{L(X_0)}$-least $m$ such that $\sigma_k{}^\frown\langle(\xi_k, m)\rangle \in G$. (If there is no such $m \in \text{field}(L(X_0))$, we take $m_k =$ least $m \notin \text{field}(L(X_0))$.) The sequence $\langle\sigma_k : k \in \mathbb{N}\rangle$ exists by primitive recursion and arithmetical comprehension, with $G$ and $L(X_0)$ as parameters. Define $\widehat{X}: \mathbb{N} \to \{0,1\}$ and $f : \mathbb{N} \to \mathbb{N}$ by $\widehat{X}(k) = \xi_k$, $f(k) = m_k$ for all $k \in \mathbb{N}$.

We claim that $f$ is an isomorphism of $L(\widehat{X})$ onto a subordering of $L(X_0)$. In other words, we are claiming that $i <_{L(\widehat{X})} j$ implies $m_i <_{L(X_0)} m_j$. Given $i <_{L(\widehat{X})} j$, recall that the field of $L(\widehat{X})$ is the tree $\mathrm{T}_A(\widehat{X})$. In view of the way $\mathrm{T}_A(X)$ was defined (lemma V.1.8), we see that $i <_{L(X)} j$ holds for any $X$ with $X[l] = \widehat{X}[l]$, $l \geq \max\{\mathrm{lh}(i), \mathrm{lh}(j)\}$. In particular, putting $l = \max\{\mathrm{lh}(i), \mathrm{lh}(j), i+1, j+1\}$, let $X$ be such that $|L(X)| = |L(X_0)|$ and, for all $k < l$, $X(k) = \xi_k$ and $|L_k(X)| = |L_{m_k}(X_0)|$. Then we have $i <_{L(X)} j$, hence $|L_{m_i}(X_0)| = |L_i(X)| < |L_j(X)| = |L_{m_j}(X_0)|$. This proves our claim.

From the above claim, we see immediately that $|L(\widehat{X})| \leq |L(X_0)|$ and, for all $k \in \mathbb{N}$, $|L_k(\widehat{X})| \leq |L_{m_k}(X_0)|$. But then, from the minimality of $|L(X_0)|$ and $|L_{m_k}(X_0)|$, it follows that $|L(\widehat{X})| = |L(X_0)|$ and $|L_k(\widehat{X})| = |L_{m_k}(X_0)|$.

We shall now show how to reformulate the above definition of $\widehat{X}$ so that it does not depend on our choice of the parameter $X_0$. Define

$$\begin{aligned}\widehat{\psi}(X) &\equiv |L(X)| = |L(X_0)| \wedge \forall k\,(X(k) = \xi_k \wedge |L_k(X)| = |L_{m_k}(X_0)|)\\ &\equiv \mathrm{WO}(L(X)) \wedge \neg\exists k\,\exists Y\,((5) \vee (6) \vee (7))\end{aligned}$$

where

(5) $|L(Y)| < |L(X)|$,

(6) $|L(Y)| = |L(X)| \wedge Y(k) < X(k) \wedge$
$(\forall i < k)\,(Y(i) = X(i) \wedge |L_i(Y)| = |L_i(X)|)$,

(7) $|L(Y)| = |L(X)| \wedge Y(k) = X(k) \wedge |L_k(Y)| < |L_k(X)| \wedge$
$(\forall i < k)\,(Y(i) = X(i) \wedge |L_i(Y)| = |L_i(X)|)$.

Then $\widehat{\psi}(X)$ is equivalent to the assertion that $X = \widehat{X}$ as above. The claims (1), (2) and (3) follow easily. Moreover $\widehat{\psi}(X)$ is explicitly a $\Pi^1_1$ formula.

This completes the proof of lemma VI.2.1. □

The following lemma is a formal version of a theorem of Suzuki. We shall make use of hyperarithmetical theory in $\mathsf{ATR}_0$ as presented in §§VII.1 and VIII.3 below.

Lemma VI.2.2 (Suzuki theorem in $\mathsf{ATR}_0$). *Let $\psi(X, Y)$ be a $\Pi^1_1$ formula with no free set variables other than $X$ and $Y$. The following is provable in $\mathsf{ATR}_0$. Suppose that $X$ and $Y$ are such that*

$$\psi(X, Y) \wedge \forall Z\, (\psi(X, Z) \to Z = Y).$$

*Then either $Y \leq_{\mathrm{H}} X$, or $\mathrm{HJ}(X)$ exists and is $\leq_{\mathrm{H}} X \oplus Y$.*

Here $Y \leq_{\mathrm{H}} X$ means that $Y$ is hyperarithmetical in $X$, and $\mathrm{HJ}(X)$ denotes the hyperjump of $X$.

Proof. Reasoning in $\mathsf{ATR}_0$, assume that $X$ and $Y$ are as above. By our formalized version of the Kleene normal form theorem (lemma V.1.4), we have

$$\forall Z\, (\psi(X, Z) \leftrightarrow \forall f\, \exists k\, \theta(X, Z[k], f[k]))$$

where $\theta(X, \sigma, \tau)$ is $\Sigma^0_0$ with no free set variables other than $X$. Let $A$ be the set of all $\langle(\eta_0, m_0), \ldots, (\eta_{k-1}, m_{k-1})\rangle$ such that $(\forall j < k)\, \eta_j < 2$ and $(\forall j \leq k)\, \neg\theta(X, \langle\eta_0, \ldots, \eta_{j-1}\rangle, \langle m_0, \ldots, m_{j-1}\rangle)$. Thus $A$ is $X$-recursive. Moreover, in the terminology of §V.1, $A$ is an analytic code and we have

$$\forall Z\, (\psi(X, Z) \leftrightarrow \mathrm{WO}(\mathrm{KB}(\mathrm{T}_A(Z)))).$$

In particular $\mathrm{KB}(\mathrm{T}_A(Y))$ is a countable $(X \oplus Y)$-recursive well ordering.

There are now two cases.

Case 1: There exists an $X$-recursive well ordering $R$ such that $|R| = |\mathrm{KB}(\mathrm{T}_A(Y))|$. In this case, $Y$ can be characterized as the unique $Z$ such that $|\mathrm{KB}(\mathrm{T}_A(Z))| = |R|$. Thus for all $n \in \mathbb{N}$ we have

$$\begin{aligned} n \in Y &\leftrightarrow \exists Z\, (|\mathrm{KB}(\mathrm{T}_A(Z))| = |R| \wedge n \in Z) \\ &\leftrightarrow \forall Z\, (|\mathrm{KB}(\mathrm{T}_A(Z))| = |R| \to n \in Z), \end{aligned}$$

so $Y$ is $\Delta^1_1$ in $X$. It follows by our formalized Kleene/Souslin theorem VIII.3.19 that $Y$ is hyperarithmetical in $X$.

Case 2: Case 1 fails. By comparability of well orderings (lemma V.2.9), it follows that $|R| < |\mathrm{KB}(\mathrm{T}_A(Y))|$ for all $X$-recursive well orderings $R$. Let $\varphi(k, X)$ be any $\Sigma^1_1$ formula with no free set variable other than $X$. We are going to show that $\{k : \varphi(k, X)\}$ exists and is $\leq_{\mathrm{H}} X \oplus Y$. By lemma V.1.4 we have

$$\forall k\, (\varphi(k, X) \leftrightarrow \exists f\, \forall m\, \theta(k, X, f[m]))$$

where $\theta(k, X, \tau)$ is $\Sigma^0_0$ with no free set variables other than $X$. Put $R_k = \mathrm{KB}(T_k)$ where $T_k$ is the set of all $\tau$ such that $(\forall m \leq \mathrm{lh}(\tau))\, \theta(k, X, \tau[m])$.

Thus $\langle R_k : k \in \mathbb{N}\rangle$ is an $X$-recursive sequence of $X$-recursive linear orderings, and for all $k$ we have

$$\begin{aligned}\varphi(k, X) &\leftrightarrow \neg \mathrm{WO}(R_k)\\ &\leftrightarrow \neg |R_k| < |\mathrm{KB}(\mathrm{T}_A(Y))|.\end{aligned}$$

Hence by $\Delta^1_1$ comprehension (lemma VIII.4.1) using $X \oplus Y$ as a parameter, there exists $W$ such that $\forall k\,(k \in W \leftrightarrow \varphi(k, X))$. Since $W$ is $\Delta^1_1$ in $X \oplus Y$, it follows by theorem VIII.3.19 that $W$ is hyperarithmetical in $X \oplus Y$. In particular, taking $\varphi(k, X)$ to be the $\Sigma^1_1$ formula which defines the hyperjump (definition VII.1.5), we see that $W = \mathrm{HJ}(X)$ exists and is $\leq_{\mathrm{H}} X \oplus Y$.

This completes the proof of lemma VI.2.2, our formalized Suzuki theorem. □

We now turn to our discussion of coanalytic sets.

Definition VI.2.3 (coanalytic sets). Within $\mathsf{RCA}_0$ we define a *coanalytic code* (i.e., a code for a coanalytic set in the Cantor space $2^{\mathbb{N}}$) to be a set $C \subseteq \mathrm{Seq}$ such that $C$ is the complement of an analytic code (definition V.1.5). In other words, there exists an analytic code $A$ such that $C = \mathrm{Seq} \setminus A$.

If $C$ is a coanalytic code, then for all $X \in 2^{\mathbb{N}}$ we write $X \in C$ to mean $\forall f\, \exists n\, C(X[n], f[n])$. Here $f$ ranges over $\mathbb{N}^{\mathbb{N}}$, and $C(X[n], f[n])$ means that $\langle (X(0), f(0)), \ldots, (X(n-1), f(n-1))\rangle \in C$. Thus $X \in C$ if and only if $X \notin A$.

The relationship between coanalytic sets and $\Pi^1_1$ formulas is given by the following lemma.

Lemma VI.2.4 (coanalytic codes and $\Pi^1_1$ formulas). *For a coanalytic code $C$, the formula $X \in C$ is $\Pi^1_1$. Conversely, for any $\Pi^1_1$ formula $\psi(X)$, $\mathsf{ACA}_0$ proves*

$$(\exists \text{ coanalytic code } C)\,\forall X\,(X \in C \leftrightarrow \psi(X)).$$

Proof. This lemma follows immediately from its dual, theorem V.1.7. □

Recall that $2^{\mathbb{N}} \times 2^{\mathbb{N}}$ is homeomorphic to $2^{\mathbb{N}}$ via the pairing function $(X, Y) \mapsto X \oplus Y$, where $(X \oplus Y)(2n) = X(n)$, $(X \oplus Y)(2n+1) = Y(n)$. Thus any coanalytic set $C \subseteq 2^{\mathbb{N}}$ may be regarded as a coanalytic relation $C \subseteq 2^{\mathbb{N}} \times 2^{\mathbb{N}}$. Formally, we write $C(X, Y)$ to mean that $X \oplus Y \in C$.

We are now ready to state and prove the main result of this section.

Definition VI.2.5 (Kondo's theorem). *Kondo's theorem* is the assertion that coanalytic sets in $2^{\mathbb{N}} \times 2^{\mathbb{N}}$ have the uniformization property. In other words, for any coanalytic code $C$, there exists a coanalytic code $\widehat{C}$ such that

(1′) $\forall X\, \forall Y\, (\widehat{C}(X, Y) \to C(X, Y))$,

$(2')$ $\forall X \forall Y (C(X, Y) \to \exists Z \widehat{C}(X, Z))$,
$(3')$ $\forall X \forall Y \forall Z ((\widehat{C}(X, Y) \wedge \widehat{C}(X, Z)) \to Y = Z)$.

Theorem VI.2.6 (Kondo's theorem and $\Pi^1_1$-$\mathsf{CA}_0$). *Kondo's theorem is equivalent over* $\mathsf{ATR}_0$ *to* $\Pi^1_1$ *comprehension*.

Proof. First, assume $\Pi^1_1$ comprehension. Let $C$ be a coanalytic code. Applying lemma VI.2.1 to the $\Pi^1_1$ formula $\psi(X, Y) \equiv C(X, Y)$ with the distinguished free set variable $Y$, we obtain a $\Pi^1_1$ formula $\widehat{\psi}(X, Y)$ such that $(1')$, $(2')$ and $(3')$ hold with $\psi$, $\widehat{\psi}$ replacing $C$, $\widehat{C}$. Then lemma VI.2.4 gives us a coanalytic code $\widehat{C}$ with the desired properties. This proves Kondo's theorem.

Now, reasoning in $\mathsf{ATR}_0$, assume Kondo's theorem. We want to prove $\Pi^1_1$ comprehension. By lemma VII.1.6, it suffices to prove that for all $X$, $\mathrm{HJ}(X)$ exists. Let $\theta(X, Y)$ be the arithmetical formula

$$\forall i \, (X \leq_{\mathrm{T}} (Y)_i \wedge \mathrm{TJ}((Y)_{i+1}) \leq_{\mathrm{T}} (Y)_i).$$

By lemmas VIII.3.23 and VIII.3.24 and the proof of lemma VIII.3.25, we have $\forall X \exists Y \, \theta(X, Y)$ and $\forall X \forall Y (\theta(X, Y) \to Y \not\leq_{\mathrm{H}} X)$. By lemma VI.2.4, let $C$ be a coanalytic code such that $\forall X \forall Y (C(X, Y) \leftrightarrow \theta(X, Y))$. By Kondo's theorem, we obtain a coanalytic code $\widehat{C}$ such that $(1')$, $(2')$ and $(3')$ hold. In particular, we have $\forall X$ ($\exists$ exactly one $Y$) $\widehat{C}(X, Y)$ and $\forall X \forall Y (\widehat{C}(X, Y) \to Y \not\leq_{\mathrm{H}} X)$.

Now given $X$, put $X' = X \oplus \widehat{C}$ (the recursive join of $X$ with the coanalytic code $\widehat{C}$), and let $Y'$ be the unique $Y$ such that $\widehat{C}(X', Y)$ holds. Since $Y' \not\leq_{\mathrm{H}} X'$, it follows by our formalized Suzuki theorem (lemma VI.2.2) that $\mathrm{HJ}(X')$ exists and is $\leq_{\mathrm{H}} X' \oplus Y'$. Hence $\mathrm{HJ}(X)$ exists by lemma VII.1.6. This proves $\Pi^1_1$ comprehension.

The proof of theorem VI.2.6 is complete. □

**Notes for §VI.2.** The original source for Kondo's theorem is Kondo [146]. The $\Pi^1_1$ uniformization principle is sometimes known as the Kondo/Addison theorem (see also Moschovakis [191] and Mansfield/Weitkamp [171]). The original source for Suzuki's theorem is Suzuki [258]. Mansfield (unpublished, but see Friedman [64, theorem 6]) has observed that Kondo's theorem and $\Pi^1_1$ uniformization are provable in $\Delta^1_2$-$\mathsf{CA}_0$ plus full induction. The fact that $\Pi^1_1$ uniformization is provable in $\Pi^1_1$-$\mathsf{CA}_0$ is due to Simpson (unpublished manuscript, January 9–10, 1981), as are the other results of this section.

## VI.3. Coanalytic Equivalence Relations

In this section we continue our investigation of classical descriptive set theory in the context of subsystems of $\mathsf{Z}_2$. We show that $\Pi^1_1$ comprehension

is necessary and sufficient to prove a famous theorem of Silver [226]: For any coanalytic equivalence relation, either the number of equivalence classes is countable or there exists a perfect set of pairwise inequivalent points. Like the perfect set theorem (§V.4), Silver's theorem may be viewed as verifying a special case of the continuum hypothesis.

We begin with the following lemma, which says that a version of Silver's theorem is provable in $\mathsf{ATR}_0$.

Lemma VI.3.1 (an $\mathsf{ATR}_0$ version of Silver's theorem). *The following is provable in* $\mathsf{ATR}_0$. *Let $E$ be a coanalytic equivalence relation. Then either*

(1) *$\exists$ perfect set $P$ such that $\forall X\, \forall Y\, ((X, Y \in P \wedge X \neq Y) \rightarrow X \not E Y)$, or*
(2) *$\exists$ sequence of Borel codes $\langle B_n : n \in \mathbb{N}\rangle$ such that $\forall X\, \exists n\, (X \in B_n)$ and $\forall n\, \forall X\, \forall Y\, ((X, Y \in B_n) \rightarrow XEY)$.*

Proof. We reason in $\mathsf{ATR}_0$. Without loss, we consider only coanalytic equivalence relations on the Cantor space $2^{\mathbb{N}}$. We prove our lemma only in a lightface form, replacing "coanalytic" by "lightface $\Pi^1_1$", and "sequence of Borel sets" by "lightface $\Delta^1_1$ sequence of lightface $\Delta^1_1$ sets", i.e., a lightface $\Delta^1_1$ subset of $\mathbb{N} \times 2^{\mathbb{N}}$. Here *lightface* means: without parameters. The full lemma is obtained from the lightface version by relativization.

We follow Harrington's [103] unpublished proof of Silver's theorem via Gandy forcing. In order to make Harrington's proof work in $\mathsf{ATR}_0$, we use an inner model technique. Throughout this argument, we use $\Sigma^1_1$ to mean lightface $\Sigma^1_1$, etc. We use an $\mathsf{ATR}_0$ formalization of hyperarithmetical theory, as presented in §VIII.3, as well as results from §VIII.4 concerning $\omega$-models of $\Sigma^1_1$-$\mathsf{AC}_0$.

We are given a $\Pi^1_1$ equivalence relation, $E$. Let $A$ be a $\Sigma^1_1$ set defined by

$$X \in A \leftrightarrow \forall \Delta^1_1 D\, (X \in D \rightarrow \exists Y (Y \in D \wedge X \not E Y)).$$

To see that this is $\Sigma^1_1$, note that by the Kleene/Souslin theorem we can represent $\Delta^1_1$ sets in the form $D = \{X : i \in \mathrm{H}^X_e\}$ where $e \in \mathcal{O}$. Thus we have

$$X \in A \leftrightarrow \forall e\, \forall i\, (\underbrace{(e \in \mathcal{O} \wedge i \in \mathrm{H}^X_e)}_{\Pi^1_1} \rightarrow \underbrace{\exists Y (i \in \mathrm{H}^Y_e \wedge X \not E Y)}_{\Sigma^1_1})$$

which is essentially $\Sigma^1_1$ (see definition VIII.6.1), hence $\Sigma^1_1$ by the $\Sigma^1_1$ axiom of choice (available in $\mathsf{ATR}_0$ by theorem V.8.3).

Case 1: $A = \emptyset$, i.e.,

$$\forall X\, \exists \Delta^1_1 D\, (X \in D \wedge \forall Y (Y \in D \rightarrow XEY)),$$

i.e.,

$$\forall X\, \exists e\, \exists i\, (\underbrace{e \in \mathcal{O} \wedge i \in \mathrm{H}^X_e \wedge \forall Y (i \in \mathrm{H}^Y_e \rightarrow XEY)}_{\Pi^1_1}).$$

Apply $\Pi^1_1$ number uniformization and $\Sigma^1_1$ separation to get a $\Delta^1_1$ sequence $\langle (e_n, i_n) : n \in \mathbb{N} \rangle$ such that $\forall n\, (e_n \in \mathcal{O})$ and

$$\forall X\, \exists n\, (i_n \in \mathrm{H}^X_{e_n} \wedge \forall Y\, (i_n \in \mathrm{H}^Y_{e_n} \to XEY)).$$

Put $B_n = \{X : i_n \in \mathrm{H}^X_{e_n}\}$. Thus in this case we have conclusion (2).

Case 2: $A \neq \emptyset$. In this case we shall obtain conclusion (1).

Define $A$ in a slightly different but equivalent way:

$$\begin{aligned} X \in A &\leftrightarrow \forall \Delta^1_1 D\, (X \in D \to \exists X_0, X_1 (X_0, X_1 \in D \wedge X_0 \not E X_1)) \\ &\leftrightarrow \forall e\, \forall i\, (\underbrace{(e \in \mathcal{O} \wedge i \in \mathrm{H}^X_e)}_{\Pi^1_1} \to \underbrace{\exists X_0, X_1 (i \in \mathrm{H}^{X_0}_e, \mathrm{H}^{X_1}_e \wedge X_0 \not E X_1)}_{\Sigma^1_1}) \\ &\quad \wedge \forall e\, (\underbrace{e \in \mathcal{O}}_{\Pi^1_1} \to \underbrace{\exists \mathrm{H}^X_e}_{\Sigma^1_1}). \end{aligned}$$

By $\Sigma^1_1$ choice we can find a countable $\omega$-model

$$M \models \mathsf{ACA}_0 \wedge \underbrace{\exists X (X \in A)}_{\text{essentially } \Sigma^1_1},$$

where we are using the previous definition of $A$.

Caution: It is probably not the case that $M \models$ "$E$ is an equivalence relation". But this will not matter.

Sublemma VI.3.2. *For any $\Sigma^1_1$ set $B$ we have*

$$M \models A \cap B \neq \emptyset \to \exists X_0, X_1\, (X_0, X_1 \in A \cap B \wedge X_0 \not E X_1).$$

Proof. We reason in $M$. Suppose the conclusion fails, i.e.,

$$\forall X_0, X_1\, (X_0, X_1 \in A \cap B \to X_0 E X_1),$$

i.e.,

$$\forall X_0\, (\underbrace{X_0 \in A \cap B}_{\Sigma^1_1} \to \underbrace{\forall X_1\, (X_1 \in A \cap B \to X_0 E X_1)}_{\Pi^1_1}).$$

By $\Sigma^1_1$ separation, there exists a $\Delta^1_1$ interpolant $D_0 = \{X : i_0 \in \mathrm{H}^X_{e_0}\}$, $e_0 \in \mathcal{O}$. Thus we have

$$\forall X_0\, (X_0 \in A \cap B \to X_0 \in D_0)$$

and

$$\forall X_0\, (X_0 \in D_0 \to \forall X_1\, (X_1 \in A \cap B \to X_0 E X_1)),$$

i.e.,

$$\forall X_1\, (\underbrace{X_1 \in A \cap B}_{\Sigma^1_1} \to \underbrace{\forall X_0\, (X_0 \in D_0 \to X_0 E X_1)}_{\Pi^1_1}).$$

By $\Sigma^1_1$ separation, there exists a $\Delta^1_1$ interpolant $D_1 = \{X\colon i_1 \in \mathrm{H}^X_{e_1}\}$, $e_1 \in \mathcal{O}$. Thus we have

$$\forall X_1\,(X_1 \in A \cap B \to X_1 \in D_1)$$

and

$$\forall X_1\,(X_1 \in D_1 \to \forall X_0\,(X_0 \in D_0 \to X_0 E X_1)).$$

Put $D = D_0 \cap D_1$. We then have

$$\forall X\,(X \in A \cap B \to X \in D)$$

and

$$\forall X_0, X_1\,(X_0, X_1 \in D \to X_0 E X_1).$$

Hence by definition of $A$ we have $A \cap D = \emptyset$. Hence $A \cap B = \emptyset$. This proves the sublemma. □

We now define Gandy forcing over $M$. A *condition* is a $\Sigma^1_1$ set $B$ such that $M \models B \neq \emptyset$. The set of all conditions is denoted $\mathcal{C}$. Note that $A$ itself is a condition, i.e., $A \in \mathcal{C}$, by case assumption and our choice of $M$. Forcing and genericity over $M$ are defined in the usual way. A set $\mathcal{D}$ of conditions is said to be *open* if $B \in \mathcal{D}$, $B' \in \mathcal{C}$, $B' \subseteq B$ imply $B' \in \mathcal{D}$. $\mathcal{D}$ is said to be *dense* if it is open and for all conditions $C$ there exists a condition $B \subseteq C$ such that $B \in \mathcal{D}$. $\mathcal{D}$ is said to be *$M$-definable* if it is definable over $M$. $X \in 2^{\mathbb{N}}$ is said to *meet* $\mathcal{D}$ if $X \in B$ for some $B \in \mathcal{D}$. $X$ is said to be *generic* if it meets all dense, $M$-definable sets of conditions. A condition $B$ is said to *force* $\varphi(X)$, abbreviated $B \Vdash \varphi(X)$, if $\varphi(X)$ holds for all generic $X \in B$. Note that for all conditions $B$ we have $B \Vdash X \in B$. We assume familiarity with basic properties of forcing and genericity.

Sublemma VI.3.3. *If $X_0 \oplus X_1$ is generic, then $X_0$ and $X_1$ are generic.*

Proof. By symmetry we consider only $X_0$. Given a dense set $\mathcal{D}_0$, we need to show that $X_0$ meets $\mathcal{D}_0$. Consider

$$\mathcal{D} = \{B \in \mathcal{C}\colon \{X_0\colon \exists X_1(X_0 \oplus X_1 \in B)\} \in \mathcal{D}_0\}.$$

We claim that $\mathcal{D}$ is dense. Given $C \in \mathcal{C}$, put $C_0 = \{X_0\colon \exists X_1(X_0 \oplus X_1 \in C)\}$. Since $\mathcal{D}_0$ is dense, there exists $B_0 \in \mathcal{D}_0$ such that $B_0 \subseteq C_0$. Put $B = \{X_0 \oplus X_1\colon X_0 \oplus X_1 \in C \wedge X_0 \in B_0\}$. Then $B \in \mathcal{D}$ and $B \subseteq C$. This proves the claim. Since $X_0 \oplus X_1$ is generic, there exists $B \in \mathcal{D}$ such that $X_0 \oplus X_1 \in B$. Then $X_0 \in \{X_0\colon \exists X_1\,(X_0 \oplus X_1 \in B)\} \in \mathcal{D}_0$. This proves the sublemma. □

We consider product Gandy forcing $\mathcal{C} \times \mathcal{C}$ over $M$. Conditions are now Cartesian products $B \times C$ where $B, C \in \mathcal{C}$. Choose an $\omega$-model $N$ which contains (the code of) $M$ and satisfies the $\Sigma^1_1$ axiom of choice. Note that $\mathrm{HYP}(M) \subseteq N$. We consider forcing and genericity over $M$ with respect

to dense sets in $N$. We define $B \times C \ \|\!\!-\ \varphi(X, Y)$ to mean that $\varphi(X, Y)$ holds for all generic $(X, Y) \in B \times C$. Note that $B \times C \ \|\!\!-\ X \in B, Y \in C$.

Sublemma VI.3.4. $A \times A \ \|\!\!-\ XE\!\!\!/\, Y$.

Proof. Suppose for a contradiction that $(X, Y) \in A \times A$ is generic and $XEY$, i.e., $\mathrm{T}_E(X, Y)$ is well founded. Thus we have $|\mathrm{T}_E(X, Y)| \leq \alpha$ for some $\alpha < \omega_1^{X \oplus Y} \leq \omega_1^M$, which we denote by $XE_\alpha Y$. (Note that $E_\alpha$ need not be an equivalence relation.) By genericity, there exist conditions $B, C \subseteq A$ such that $B \times C \ \|\!\!-\ XE_\alpha Y$. Put $B' = \{X_0 \oplus X_1 \colon X_0, X_1 \in B, X_0 E\!\!\!/\, X_1\}$. By sublemma VI.3.2 we have $M \models (B' \neq \emptyset)$. Let $(X_0 \oplus X_1, Y) \in B' \times C$ be generic. By a variant of sublemma VI.3.3, $(X_0, Y)$ and $(X_1, Y)$ are generic. Since $(X_0, Y), (X_1, Y) \in B \times C$, we have $X_0 E_\alpha Y$, $X_1 E_\alpha Y$, $X_0 E\!\!\!/\, X_1$, a contradiction. This proves the sublemma. □

Now starting with $A$ we can build a full binary tree of conditions so that each pair of paths is generic. Since each pair of paths belongs to $A \times A$, sublemma VI.3.4 implies that we have a perfect set $P$ such that

$$\forall X \, \forall Y \, ((X \in P \wedge Y \in P \wedge X \neq Y) \rightarrow XE\!\!\!/\, Y).$$

This completes the proof of lemma VI.3.1. □

Definition VI.3.5 (Silver's theorem). By *Silver's theorem* we mean the following statement: If $E$ is a coanalytic equivalence relation, then either VI.3.1(1) holds, or

(2′) $\exists$ sequence of points $\langle Y_n \colon n \in \mathbb{N} \rangle$ such that $\forall X \, \exists n \, (XE Y_n)$.

Theorem VI.3.6 (Silver's theorem and $\Pi^1_1$-$\mathsf{CA}_0$). *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

(i) $\Pi^1_1$ *comprehension*.
(ii) *Silver's theorem*.
(iii) *Silver's theorem restricted to equivalence relations on* $\mathbb{N}^\mathbb{N}$ *which are* $\Delta^0_2$ *definable* (*with parameters, of course*).

Proof. Since $\Pi^1_1$-$\mathsf{CA}_0$ includes $\mathsf{ATR}_0$, lemma VI.3.1 implies that $\Pi^1_1$-$\mathsf{CA}_0$ proves (1) $\vee$ (2) for any coanalytic equivalence relation $E$. But if (2) holds, then we can use $\Pi^1_1$ comprehension to form $\{n \colon B_n \neq \emptyset\}$, followed by $\Sigma^1_1$ choice to obtain a sequence of points $\langle Y_n \colon n \in \mathbb{N} \rangle$ such that $\forall n \, (B_n \neq \emptyset \rightarrow Y_n \in B_n)$, and this gives (2′). Thus we see that $\Pi^1_1$-$\mathsf{CA}_0$ proves (1) $\vee$ (2′). We have shown (i)→(ii), and (ii)→(iii) is trivial.

For the reversal, we reason in $\mathsf{RCA}_0$ and assume (iii). As in the proof of lemma VI.1.1, it is easy to show that (iii) implies arithmetical comprehension. Given a $\Sigma^1_1$ formula $\varphi(m)$, use the Kleene normal form theorem (lemma V.1.4) to write $\varphi(m) \equiv \exists f \, \theta(m, f)$, $f \in \mathbb{N}^\mathbb{N}$, where $\theta(m, f)$ is $\Pi^0_1$. Define a $\Delta^0_2$ equivalence relation $E$ on $\mathbb{N} \times \mathbb{N}^\mathbb{N} \cong \mathbb{N}^\mathbb{N}$ by putting

$$(m, f) E (n, g) \equiv m = n \wedge (\theta(m, f) \leftrightarrow \theta(n, g)).$$

Clearly (1) does not hold for this equivalence relation, so by (2′) let $\langle Y_k : k \in \mathbb{N}\rangle$ be a sequence of points of $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}$ such that $\forall m \forall f \exists k$ $((m, f) E Y_k)$. Put $Y_k = (m_k, f_k)$. Then $\forall m (\exists f\, \theta(m, f) \leftrightarrow \exists k (m = m_k \wedge \theta(m, f_k))$. Hence $\{m : \varphi(m)\} = \{m : \exists f\, \theta(m, f)\}$ exists by arithmetical comprehension, using $\langle (m_k, f_k) : k \in \mathbb{N}\rangle$ as a parameter. This proves $\Sigma^1_1$ comprehension, hence (i). □

**Notes for §VI.3.** Silver's original proof of Silver's theorem [226] used transfinitely many iterations of the power set axiom in ZFC. The fact that Silver's theorem is provable in $Z_2$ is due to Harrington [103]. Other applications of Harrington's method are in Louveau [164]. The reversal in theorem VI.3.6 is due to Ramez Sami (personal communication, June 1981). Lemma VI.3.1 and theorem VI.3.6 are due to Simpson (unpublished notes, March 17, 1984). For another treatment of lemma VI.3.1 and related results, see Marcone [172]. Other results related to Silver's theorem are in Harrington/Marker/Shelah [105], Louveau [165], and Louveau/Saint-Raymond [166].

## VI.4. Countable Abelian Groups

In this section we show that $\Pi^1_1$-$\mathsf{CA}_0$ is equivalent over $\mathsf{RCA}_0$ to a well known theorem concerning the structure of countable Abelian groups. Our result is as follows:

Theorem VI.4.1 ($\Pi^1_1$-$\mathsf{CA}_0$ and countable Abelian groups). *The following are equivalent over* $\mathsf{RCA}_0$.

1. $\Pi^1_1$ *comprehension*.
2. *Every countable Abelian group is a direct sum of a divisible group and a reduced group.*

Proof. We shall need the following lemma.

Lemma VI.4.2. *The following is provable in* $\mathsf{ACA}_0$. *If $D$ is a divisible subgroup of a countable Abelian group $G$, then $G = D \oplus A$ for some subgroup $A$.*

Proof. By injectivity (theorem III.6.5) there is a homomorphism $h : G \to D$ such that $h(d) = d$ for all $d \in D$. Letting $A$ be the kernel of $h$, i.e., $A = \{a \in G : h(a) = 0\}$, we easily see that $G = D \oplus A$. This proves the lemma. □

Now to prove theorem VI.4.1, assume $\Pi^1_1$-$\mathsf{CA}_0$ and let $G$ be an Abelian group. Let us define an element $d \in G$ to be *divisible* if for each prime $p$ there exists $f : \mathbb{N} \to G$ such that $f(0) = d$ and $\forall n (pf(n + 1) = f(n))$. Being divisible is a $\Sigma^1_1$ property, so by $\Sigma^1_1$ comprehension, $D = \{d \in G :$ $d$ is divisible$\}$ exists. Clearly $D$ is a subgroup of $G$ and is $p$-divisible for all primes $p$. By an easy application of $\Sigma^0_1$ induction, it follows that $D$ is

divisible. By lemma VI.4.2 we have $G = D \oplus A$, and clearly $A$ is reduced. This proves $1 \to 2$.

For the converse, we reason in $\mathsf{RCA}_0$. We begin with:

Lemma VI.4.3. *It is provable in* $\mathsf{RCA}_0$ *that statement* 2 *implies arithmetical comprehension.*

Proof. Reasoning in $\mathsf{RCA}_0$, let $f : \mathbb{N} \to \mathbb{N}$ be one-to-one. Let $G$ be the Abelian group with generators $x_m$, $y_{m,i}$, $m, i \in \mathbb{N}$ and relations $px_m = 0$, $py_{m,i+1} = y_{m,i}$, $py_{m,0} = x_{f(m)}$. The elements of $G$ can be written in normal form as finite sums $\sum k_{m,i} y_{m,i} + \sum l_m x_m$, $0 < k_{m,i} < p$. By our assumption 2 we have $G = D \oplus R$ where $D$ is divisible and $R$ is reduced.

We claim that, for each $n \in \mathbb{N}$, $x_n \in D$ if and only if $n \in \mathrm{rng}(f)$. To see this, suppose $x_n \in D$ and let $d = \sum k_{m,i} y_{m,i} + \sum l_m x_m$ be in $D$ with $pd = x_n$. Note that

$$pd = \sum_{i>0} k_{m,i} y_{m,i-1} + \sum_{i=0} k_{m,i} x_{f(m)} = x_n.$$

By uniqueness of the normal form, we have $k_{m,i} = 0$ for $i > 0$, $k_{m,0} = 0$ for $m$ such that $f(m) \neq n$, and $k_{m,0} = 1$ for $m$ such that $f(m) = n$. Thus $n \in \mathrm{rng}(f)$. Conversely, suppose $n = f(m)$ for some $m$. Then the sequence $y_{m,0}, y_{m,1}, \ldots$ $p$-divides $x_n$. If $x_n \notin D$, then using $G = D \oplus R$ we have $x_n = d + r$ and $y_{m,i} = d_i + r_i$ for each $i$. It follows that $pr_{i+1} = r_i$ for all $i$, and $pr_0 = r \neq 0$. Let $A$ be the subgroup generated by $r_0, r_1, \ldots$. It is easy to see that $A$ exists, $A$ is divisible, and $A \subseteq R$, a contradiction.

The claim implies that $\mathrm{rng}(f)$ exists. By lemma III.1.3 this gives arithmetical comprehension, Q.E.D. □

Now we use 2 plus arithmetical comprehension to prove $\Pi^1_1$ comprehension. Given a tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$, let $G$ be the Abelian group with generators $x_\tau$, $\tau \in T$, and relations $px_\tau = x_\sigma$, $\tau = \sigma^\frown\langle i\rangle$, and $x_{\langle\rangle} = 0$. The elements of $G$ can be written in normal form as finite sums $\sum k_\tau x_\tau$ where $0 < k_\tau < p$. By our assumption 2, $G$ can be decomposed as $D \oplus R$ where $D$ is divisible and $R$ is reduced. By lemma VI.4.2, $D$ is the union of all divisible subgroups of $G$.

We claim that $\tau \in T$ lies on a path of $T$ if and only if $x_\tau \in D$. To see this, note first that if $f$ is a path through $T$ then the subgroup $A$ generated by $x_{f[n]}$, $n \in \mathbb{N}$ is divisible, hence $A \subseteq D$. Conversely, if $x_\tau \in D$, use primitive recursion to define a sequence $d_n \in D$, $n \in \mathbb{N}$, where $d_0 = x_\tau$ and $pd_{n+1} = d_n$ for all $n$. If $d_n = \sum k_\sigma x_\sigma$ and $d_{n+1} = \sum l_\rho x_\rho$, then $d_n = \sum k_\sigma x_\sigma = pd_{n+1} = \sum pl_\rho x_\rho$, from which it follows that each $\sigma$ appearing in $d_n$ is a proper initial segment of some $\rho$ appearing in $d_{n+1}$. By primitive recursion there exists a sequence $\sigma_n$, $n \in \mathbb{N}$, such that $\sigma_0 = \tau$ and for all $n$, $\sigma_n$ appears in $d_n$ and is a proper initial segment of $\sigma_{n+1}$. Thus $\tau$ lies on a path through $T$. This proves our claim.

Since $D$ exists, our claim implies the existence of $\widehat{T} = \{\tau\colon \tau \text{ lies on a path of } T\}$. This gives $\Pi^1_1$ comprehension, in view of the following easy lemma.

LEMMA VI.4.4. *$\Pi^1_1$ comprehension is equivalent over $\mathsf{RCA}_0$ to the following statement $S$: For any tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$, there exists a subtree*

$$\widehat{T} = \{\tau\colon \tau \text{ lies on a path of } T\}.$$

PROOF. Obviously $\Pi^1_1$-$\mathsf{CA}_0$ proves statement $S$. For the converse, assume statement $S$ and let $\langle T_k : k \in \mathbb{N}\rangle$ be an arbitrary sequence of trees. Form a tree

$$T = \{\langle\rangle\} \cup \{\langle k\rangle^\frown \tau\colon k \in \mathbb{N}, \tau \in T_k\}.$$

By statement $S$, $\widehat{T}$ exists. We have $\forall k\, (\langle k\rangle \in \widehat{T} \leftrightarrow T_k \text{ has a path})$, hence by $\Delta^0_1$ comprehension $\{k\colon T_k \text{ has a path}\}$ exists. Now lemma VI.1.1 gives $\Pi^1_1$ comprehension. Lemma VI.4.4 is proved. □

The proof of theorem VI.4.1 is now complete. □

REMARK VI.4.5. Combining theorem VI.4.1 with the results of §§III.6 and V.7, we see that $\Pi^1_1$-$\mathsf{CA}_0$ is necessary and sufficient for the development of the structure theory of countable Abelian groups, although $\mathsf{ACA}_0$ and $\mathsf{ATR}_0$ suffice for certain parts of the theory. Such conclusions are typical of Reverse Mathematics.

**Notes for §VI.4.** A nice exposition of the structure theory of countable Abelian groups is in Kaplansky [136]. The construction used in the last part of the proof of theorem VI.4.1 is from Feferman [58]. The theorem itself is due to Friedman/Simpson/Smith [78].

## VI.5. $\Sigma^0_1 \wedge \Pi^0_1$ Determinacy

We have seen in §V.8 that arithmetical transfinite recursion is equivalent to $\Sigma^0_1$ determinacy. We shall now show that $\Pi^1_1$ comprehension is equivalent to a stronger statement, namely $\Sigma^0_1 \wedge \Pi^0_1$ determinacy.

DEFINITION VI.5.1 ($\Sigma^0_1 \wedge \Pi^0_1$ determinacy). A formula $\theta$ is $\Sigma^0_1 \wedge \Pi^0_1$ if it is of the form $\varphi \wedge \psi$ where $\varphi$ is $\Sigma^0_1$ and $\psi$ is $\Pi^0_1$. $\Sigma^0_1 \wedge \Pi^0_1$ *determinacy* is the scheme

$$\exists S_0\, \forall S_1\, \theta(S_0 \otimes S_1) \vee \exists S_1\, \forall S_0\, \neg\theta(S_0 \otimes S_1)$$

where $\theta(f)$ is $\Sigma^0_1 \wedge \Pi^0_1$. Here $S_0$ and $S_1$ are variables ranging over 0-strategies and 1-strategies respectively, as in §V.8.

LEMMA VI.5.2. *$\Pi^1_1$-$\mathsf{CA}_0$ proves $\Sigma^0_1 \wedge \Pi^0_1$ determinacy.*

PROOF. We reason in $\Pi^1_1$-$\mathsf{CA}_0$. Let

$$\psi(f) \equiv \varphi_0(f) \wedge \neg\varphi_1(f)$$

be a $\Sigma^0_1 \wedge \Pi^0_1$ formula, where $\varphi_0$ and $\varphi_1$ are $\Sigma^0_1$. We shall prove

$$\exists S'_0\, \forall S_1\, \psi(S'_0 \otimes S_1) \vee \exists S'_1\, \forall S_0\, \neg\psi(S_0 \otimes S'_1).$$

By the Kleene normal form theorem V.1.4, we have $\varphi_i(f) \equiv \exists n\, \theta_i(f[n])$, where $\theta_i(\sigma)$ is arithmetical. Recall from §V.8 that

$$\mathrm{Seq}_0 = \{\sigma \in \mathrm{Seq} \colon \mathrm{lh}(\sigma) \text{ is even}\}.$$

We may safely assume that $\varphi_i(f) \equiv \exists n\, \theta_i(f[2n])$ and that

$$(\forall \sigma \in \mathrm{Seq}_0)\, \forall n\, ((\theta_i(\sigma) \wedge 2n < \mathrm{lh}(\sigma)) \to \neg\theta_i(\sigma[2n])).$$

For $\sigma \in \mathrm{Seq} = \mathbb{N}^{<\mathbb{N}}$ and $f \in \mathbb{N}^{\mathbb{N}}$, let $\sigma^\frown f$ be the concatenation, i.e., $\sigma^\frown f \in \mathbb{N}^{\mathbb{N}}$ where

$$(\sigma^\frown f)(n) = \begin{cases} \sigma(n) & \text{if } n < \mathrm{lh}(\sigma), \\ f(n - \mathrm{lh}(\sigma)) & \text{if } n \geq \mathrm{lh}(\sigma). \end{cases}$$

Put $\varphi^\sigma_i(f) \equiv \varphi_i(\sigma^\frown f)$ and $\theta^\sigma_i(\tau) \equiv \theta_i(\sigma^\frown \tau)$. Note that $\varphi^\sigma_i(f) \equiv \exists n\, \theta^\sigma_i(f[2n])$.

Define

$$P = \{\sigma \in \mathrm{Seq}_0 \colon \theta_0(\sigma) \wedge \exists S_0\, \forall S_1\, \neg\varphi^\sigma_1(S_0 \otimes S_1)\}.$$

We claim that $P$ exists by $\Sigma^1_1$ comprehension. To see this, it suffices to show that $\forall S_1\, \neg\varphi^\sigma_1(S_0 \otimes S_1)$ is equivalent to an arithmetical formula. Let us say that $\tau \in \mathrm{Seq}_0$ is *compatible with* $S_0$ if $\forall n\, (2n < \mathrm{lh}(\tau) \to \tau(2n) = S_0(\tau[2n]))$. Then $\forall S_1\, \neg\varphi^\sigma_1(S_0 \otimes S_1)$ is equivalent to $\forall S_1\, \forall n\, \neg\theta^\sigma_1((S_0 \otimes S_1)[2n])$, i.e.,

$$(\forall \tau \in \mathrm{Seq}_0)\, (\tau \text{ compatible with } S_0 \to \neg\theta^\sigma_1(\tau)),$$

which is arithmetical. This proves our claim, i.e., $P$ exists.

Now consider the $\Sigma^0_1$ formula $\varphi(f) \equiv \exists n\, (f[2n] \in P)$, with parameter $P$. By theorem V.8.7 we have $\Sigma^0_1$ determinacy in $\Pi^1_1$-$\mathsf{CA}_0$, hence either $\exists S_0\, \forall S_1\, \exists n\, ((S_0 \otimes S_1)[2n] \in P)$ or $\exists S_1\, \forall S_0\, \forall n\, ((S_0 \otimes S_1)[2n] \notin P)$.

Case 1: $\exists S_0\, \forall S_1\, \exists n\, ((S_0 \otimes S_1)[2n] \in P)$. Fix such a 0-strategy $S_0$. By $\Sigma^1_1$ choice, there exists a sequence of 0-strategies $\langle S^\sigma_0 \colon \sigma \in P\rangle$ such that $(\forall \sigma \in P)\, \forall S_1\, \neg\varphi^\sigma_1(S^\sigma_0 \otimes S_1)$. Note that $\Sigma^1_1$ choice applies in this situation, because as we have seen above, the formula $\forall S_1\, \neg\varphi^\sigma_1(S_0 \otimes S_1)$ is equivalent to an arithmetical formula. Now define a 0-strategy $S'_0$ by putting $S'_0(\tau) = S_0(\tau)$ for all $\tau \in \mathrm{Seq}_0$ such that $\forall n\, (2n \leq \mathrm{lh}(\tau) \to \tau[2n] \notin P)$, and $S'_0(\sigma^\frown \tau) = S^\sigma_0(\tau)$ for all $\sigma \in P$ and all $\tau \in \mathrm{Seq}_0$.

Let $S_1$ be any 1-strategy. Then there exists a unique $n$ such that $(S'_0 \otimes S_1)[2n] \in P$. In particular $\varphi_0(S'_0 \otimes S_1)$ holds. Moreover, putting $\sigma = (S'_0 \otimes S_1)[2n]$ for this $n$, we have $S'_0 \otimes S_1 = \sigma^\frown f$ where $\forall m\, (f[2m]$ is

compatible with $S_0^\sigma$). It follows that $\neg\varphi_1^\sigma(f)$ holds, i.e., $\neg\varphi_1(S_0' \otimes S_1)$. Thus in this case we have $\forall S_1\, \psi(S_0' \otimes S_1)$.

Case 2: $\exists S_1\, \forall S_0\, \forall n\, ((S_0 \otimes S_1)[2n] \notin P)$. Fix such a 1-strategy $S_1$. Define $Q = \{\sigma \in \mathrm{Seq}_0 : \theta_0(\sigma) \wedge \sigma \notin P\}$. By $\Sigma^0_1$ determinacy we have that for all $\sigma \in Q$ there exists a 1-strategy $\widetilde{S_1}$ such that $\forall S_0\, \varphi_1^\sigma(S_0 \otimes \widetilde{S_1})$.

We claim that a choice principle applies, i.e., there exists a sequence of 1-strategies $\langle \widetilde{S_1^\sigma} : \sigma \in Q\rangle$ such that $(\forall \sigma \in Q)\, \forall S_0\, \varphi_1^\sigma(S_0 \otimes \widetilde{S_1^\sigma})$. To see this, we use an inner model. Let $M$ be a countable coded $\beta$-model containing all the parameters of the formula $\varphi_1(f)$ (theorem VII.2.10). Then $M \models \mathsf{ATR}_0$ (theorem VII.2.7). Hence $M \models \Sigma^0_1$ determinacy (theorem V.8.7). For each $\sigma \in Q$ we have $\neg\exists S_0\, \forall \widetilde{S_1}\, \neg\varphi_1^\sigma(S_0 \otimes \widetilde{S_1})$, and this can be written as a $\Pi^1_1$ formula, hence it holds in $M$, since $M$ is a $\beta$-model. It now follows by $\Sigma^0_1$ determinacy in $M$ that, for each $\sigma \in Q$, $M \models \exists \widetilde{S_1}\, \forall S_0\, \varphi_1^\sigma(S_0 \otimes \widetilde{S_1})$. Using the code of $M$ as a parameter, we obtain a sequence of 1-strategies $\langle \widetilde{S_1^\sigma} : \sigma \in Q\rangle$ such that, for each $\sigma \in Q$, $\widetilde{S_1^\sigma} \in M$ and $M \models \forall S_0\, \varphi_1^\sigma(S_0 \otimes \widetilde{S_1^\sigma})$. Since $M$ is a $\beta$-model, it follows that for each $\sigma \in Q$, $\forall S_0\, \varphi_1^\sigma(S_0 \otimes \widetilde{S_1^\sigma})$ is true. This proves our claim.

Now define a 1-strategy $S_1'$ by putting $S_1'(\tau) = S_1(\tau)$ for all $\tau \in \mathrm{Seq}_1$ such that $\forall n(2n < \mathrm{lh}(\tau) \to \neg\theta_0(\tau[2n]))$, and $S_1'(\sigma^\frown\tau) = \widetilde{S_1^\sigma}(\tau)$ for all $\tau \in \mathrm{Seq}_1$ and all $\sigma \in \mathrm{Seq}_0$ such that $\theta_0(\sigma)$ holds.

Let $S_0$ be any 0-strategy. We have $\forall n\, (S_0 \otimes S_1')[2n] \notin P$. If $\forall n\, \neg\theta_0(S_0 \otimes S_1')[2n])$ then we have $\neg\varphi_0(S_0 \otimes S_1')$. Otherwise there is a unique $n$ such that $(S_0 \otimes S_1')[2n] \in Q$. Putting $\sigma = (S_0 \otimes S_1')[2n]$ for this $n$, we have $S_0 \otimes S_1' = \sigma^\frown f$ where $\forall m\, (f[2m]$ is compatible with $\widetilde{S_1^\sigma})$. It follows that $\varphi_1^\sigma(f)$ holds, i.e., $\varphi_1(S_0 \otimes S_1')$. Thus in this case we have $\forall S_0\, \neg\psi(S_0 \otimes S_1')$.

This completes the proof of lemma VI.5.2. □

We now turn to the reversal.

Lemma VI.5.3. *It is provable in* $\mathsf{RCA}_0$ *that* $\Sigma^0_1 \wedge \Pi^0_1$ *determinacy implies* $\Pi^1_1$ *comprehension*.

Proof. Assume $\Sigma^0_1 \wedge \Pi^0_1$ determinacy. By lemma V.8.5 we have arithmetical comprehension. We shall prove $\Pi^1_1$ comprehension. Our proof will be analogous to the proof of lemma V.8.5. By lemma VI.1.1 it suffices to show: given any sequence of trees $\langle T_k : k \in \mathbb{N}\rangle$, there exists a set $X$ such that $\forall k\, (k \in X \leftrightarrow T_k$ has a path). Without loss of generality, we may assume $\forall k\, (\langle\rangle \in T_k)$.

Intuitively, consider the following game. Player 0 chooses an integer $k = f(0)$. Then player 1 attempts to build a path $f(1), f(3), \ldots$ through $T_k$. If player 1 succeeds, he wins the game. Otherwise, player 0 waits until the first $n$ such that $\langle f(1), f(3), \ldots, f(2n+1)\rangle \notin T_k$. Then player 0 attempts to build a path $f(2n+2), f(2n+4), \ldots$ through $T_k$. If player 0 succeeds, he wins the game. Otherwise, player 1 wins the game.

It is clear that player 0 cannot have a winning strategy. Hence, by $\Sigma^0_1 \wedge \Pi^0_1$ determinacy, player 1 has a winning strategy; call it $S_1$. Let $g_k(0)$, $g_k(1), \ldots$ be the sequence $f(1), f(3), \ldots$ chosen by player 1 according to $S_1$ when player 0 begins the game with $f(0) = k$. Then

$$\forall k\,(T_k \text{ has a path} \to g_k \text{ is a path through } T_k).$$

Hence the desired set $X$ exists by arithmetical comprehension with parameters $\langle T_k : k \in \mathbb{N}\rangle$ and $\langle g_k : k \in \mathbb{N}\rangle$. This proves $\Pi^1_1$ comprehension.

We now formalize the above intuitive argument.

Formally, let $\theta(f)$ be the following $\Sigma^0_1 \wedge \Pi^0_1$ formula:

$$\begin{aligned}
&\exists n\,(\langle f(1), f(3), \ldots, f(2n+1)\rangle \notin T_{f(0)}) \wedge \\
&\forall m\,\forall n((\langle f(1), f(3), \ldots, f(2n-1)\rangle \in T_{f(0)} \wedge \\
&\qquad \langle f(1), f(3), \ldots, f(2n+1)\rangle \notin T_{f(0)}) \to \\
&\qquad\qquad (\langle f(2n+2), f(2n+4), \ldots, f(2n+2m)\rangle \in T_{f(0)})).
\end{aligned}$$

We claim that $\forall S_0\,\exists S_1 \neg\theta(S_0 \otimes S_1)$. To see this, let $S_0$ be given and set $k = S_0(\langle\rangle)$. If $T_k$ has a path, let $g$ be such a path and put $S_1(\sigma) = g(n)$ for all $\sigma$ of length $2n+1$. Otherwise let $S_1 : \mathrm{Seq}_1 \to \mathbb{N}$ be arbitrary. Putting $f = S_0 \otimes S_1$ we have in the first case

$$\forall n\,(\langle f(1), f(3), \ldots, f(2n+1)\rangle = \langle g(0), g(1), \ldots, g(n)\rangle \in T_k = T_{f(0)}),$$

and in the second case

$$\forall n\,\exists m\,(\langle f(2n+2), f(2n+4), \ldots, f(2n+2m)\rangle \notin T_k = T_{f(0)}).$$

In either case $\neg\theta(f)$. This proves our claim.

Hence by $\Sigma^0_1 \wedge \Pi^0_1$ determinacy there exists $S_1$ such that $\forall S_0\,\neg\theta(S_0 \otimes S_1)$. For all $k$ define $g_k : \mathbb{N} \to \mathbb{N}$ recursively by

$$g_k(n) = S_1(\langle k, g_k(0), 0, g_k(1), 0, \ldots, g_k(n-1), 0\rangle).$$

We claim that $\forall k$ (if $T_k$ has a path, then $g_k$ is a path through $T_k$). Suppose not. Let $k$, $n$, and $h$ be such that $g_k[n] \in T_k$ and $g_k[n+1] \notin T_k$ and $\forall m(h[m] \in T_k)$. Define $S_0(\langle\rangle) = k$, $S_0(\sigma) = 0$ for $\sigma$ of length $2m+2 < 2n+2$, and $S_0(\sigma) = h(m)$ for $\sigma$ of length $2n+2m+2$, for all m. Then clearly $\theta(S_0 \otimes S_1)$ holds, a contradiction. This proves our claim.

By arithmetical comprehension let $X$ be such that $\forall k\,(k \in X \leftrightarrow g_k$ is a path through $T_k)$. The previous claim implies that $\forall k\,(k \in X \leftrightarrow T_k$ has a path). This completes the proof of lemma VI.5.3. □

Summarizing, we have

THEOREM VI.5.4. *The following are equivalent over* $\mathsf{RCA}_0$.

1. $\Pi^1_1$ *comprehension*.
2. $\Sigma^0_1 \wedge \Pi^0_1$ *determinacy*.

PROOF. This is immediate from lemmas VI.5.2 and VI.5.3. □

**Notes for §VI.5.** Theorem VI.5.4 is from Tanaka [263]. Earlier Steel [256, page 24] had announced that $\Pi^1_1$ comprehension is equivalent to determinacy for Boolean combinations of $\Sigma^0_1$ formulas, but the details have not appeared. Other related results are in Tanaka [264]. See also §§V.8 and VI.7.

## VI.6. The $\Delta^0_2$ Ramsey Theorem

We have seen in §V.9 that arithmetical transfinite recursion is equivalent to the $\Sigma^0_1$ Ramsey theorem. We shall now show that $\Pi^1_1$ comprehension is equivalent to the $\Delta^0_2$ Ramsey theorem, and to the arithmetical or $\Sigma^0_\infty$ Ramsey theorem. See theorem VI.6.4 below.

We begin with the reversal.

Lemma VI.6.1. *It is provable in* $\mathsf{RCA}_0$ *that* $\Delta^0_2$-RT *implies* $\Pi^1_1$ *comprehension*.

Proof. Reasoning in $\mathsf{RCA}_0$, assume the $\Delta^0_2$ Ramsey theorem, $\Delta^0_2$-RT (definition V.9.1). Trivially $\Delta^0_2$-RT implies RT(3), hence by lemma III.7.5 we have arithmetical comprehension. We want to prove $\Pi^1_1$ comprehension. Let $\langle T_m : m \in \mathbb{N}\rangle$ be a sequence of trees. By lemma VI.1.1 it suffices to prove the existence of the set $\{m : T_m \text{ has a path}\}$.

Recall from §V.9 the notion of a tree $T$ being majorized by a function $f \in [\mathbb{N}]^{\mathbb{N}}$ or by a finite sequence $\sigma \in [\mathbb{N}]^{<\mathbb{N}}$. Note also that, by bounded König's lemma, $f$ majorizes $T$ if only if $\forall n\,(f[n]$ majorizes $T)$. Thus "$f$ majorizes $T$" can be written as a $\Pi^0_1$ formula. Moreover, $T$ has a path if and only if $\exists f \in [\mathbb{N}]^{\mathbb{N}}$ such that $f$ majorizes $T$.

For $k \in \mathbb{N}$ and $f \in [\mathbb{N}]^{\mathbb{N}}$, define $f^{(k)} \in [\mathbb{N}]^{\mathbb{N}}$ by $f^{(k)}(n) = f(k+n)$. Write

$$\varphi(f) \equiv (\forall m < f(0))\,(f^{(1)} \text{ majorizes } T_m \leftrightarrow f^{(2)} \text{ majorizes } T_m).$$

Note that $\varphi(f)$ can be written in either $\Sigma^0_2$ or $\Pi^0_2$ form, i.e., $\varphi(f)$ is $\Delta^0_2$. By $\Delta^0_2$-RT, let $h \in [\mathbb{N}]^{\mathbb{N}}$ be homogeneous for $\varphi(f)$, i.e., either $(\forall g \in [\mathbb{N}]^{\mathbb{N}})\,\varphi(h \cdot g)$ or $(\forall g \in [\mathbb{N}]^{\mathbb{N}})\,\neg\varphi(h \cdot g)$.

Claim 1: $\varphi(h \cdot g)$ holds for all $g \in [\mathbb{N}]^{\mathbb{N}}$.

If not, then $\neg\varphi(h \cdot g)$ holds for all $g \in [\mathbb{N}]^{\mathbb{N}}$, hence in particular for each $n \in \mathbb{N}$ there exists $m < h(0)$ such that $T_m$ is majorized by $h^{(n+2)}$ but not by $h^{(n+1)}$. Mapping $n$ to the least such $m$, we would obtain a one-to-one function from $\mathbb{N}$ into $\{0, 1, \ldots, h(0)-1\}$, contradiction.

Claim 2: For each $m \in \mathbb{N}$, if $T_m$ has a path then $T_m$ is majorized by $h^{(m+2)}$.

Suppose not, i.e., $T_m$ has a path but $h^{(m+2)}$ does not majorize $T_m$. Let $n \in \mathbb{N}$ be such that $h^{(m+2)}[n]$ does not majorize $T_m$. Let $g \in [\mathbb{N}]^{\mathbb{N}}$ be such

that $g$ majorizes $T_m$. Put

$$f = h^{(m+1)}[n+1]^\frown(h^{(m+n+2)} \cdot g).$$

Then $T_m$ is majorized by $f^{(n+1)} = (h^{(m+n+2)} \cdot g)$ but is not majorized by $f^{(1)} = h^{(m+2)}[n]^\frown(h^{(m+n+2)} \cdot g)$. This is a contradiction, since we have $m < h(m+1) = f(0)$ and therefore, by claim 1, for all $k \geq 1$, $f^{(k)}$ majorizes $T_m$ if and only if $f^{(k+1)}$ majorizes $T_m$. Thus we have proved claim 2.

By claim 2 we have

$$\forall m\,(T_m \text{ has a path} \leftrightarrow T_m \text{ is majorized by } h^{(m+2)}).$$

Hence $\{m\colon T_m \text{ has a path}\}$ exists, by arithmetical comprehension with $h$ as a parameter. This completes the proof of lemma VI.6.1. □

We shall now show that, for all $k \in \omega$, $\Sigma^0_k$-RT is provable in $\Pi^1_1$-$\mathsf{CA}_0$. We use an inner model technique. Our proof is based on the following lemma, which employs the notion of countable coded $\beta$-model from §VII.2. If $M_1$ and $M_2$ are countable coded $\beta$-models, $M_1 \in M_2$ means that the code of $M_1$ is an element of $M_2$.

LEMMA VI.6.2. *The following is provable in* $\mathsf{ACA}_0$. *Let* $M_1, \ldots, M_k$ *be a finite sequence of countable coded* $\beta$*-models such that*

$$M_1 \in \cdots \in M_k.$$

*Then for any* $\Sigma^0_k$ *formula* $\varphi(f)$ *with parameters in* $M_1$, *there exists* $h \in M_k$ *such that* $\forall g\,\varphi(h \cdot g) \vee \forall g\,\neg\varphi(h \cdot g)$. *Here* $f$, $g$, *and* $h$ *range over* $[\mathbb{N}]^{\mathbb{N}}$.

PROOF. We reason in $\mathsf{ACA}_0$ and proceed by induction on $k \geq 1$. For $\Sigma^0_1$ formulas, our result follows from $\Sigma^0_1$-RT in $\mathsf{ATR}_0$ (theorem V.9.7) plus the fact that any countable coded $\beta$-model satisfies $\mathsf{ATR}_0$ (theorem VII.2.7). We inductively assume our result for $\Sigma^0_k$ formulas and prove and prove it for $\Sigma^0_{k+1}$ formulas, $k \geq 1$.

Let $M_1 \in \cdots \in M_k \in M_{k+1}$ be countable coded $\beta$-models. Let $\varphi(f)$ be a $\Sigma^0_{k+1}$ formula with parameters in $M_1$. Write

$$\varphi(f) \equiv \exists n_1\,\forall n_2 \cdots n_k\,\psi(n_1, n_2, \ldots, n_k, f)$$

where $\psi(n_1, \ldots, n_k, f)$ is $\Sigma^0_1$ or $\Pi^0_1$, depending on whether $k$ is even or odd, with parameters in $M_1$.

Within $M_2$, by recursion on $n \in \mathbb{N}$ using the code of $M_1$ as a parameter, define sequences $\sigma_n \in [\mathbb{N}]^{<\mathbb{N}}$, $f_n \in M_1 \cap [\mathbb{N}]^{\mathbb{N}}$, $n \in \mathbb{N}$, as follows. We employ the concatenation notation $\sigma^\frown f$ as in §VI.5. For each $n \in \mathbb{N}$ we shall have $\sigma_n{}^\frown f_n \in [\mathbb{N}]^{\mathbb{N}}$. Begin with $\sigma_0 = \langle\rangle$ and $f_0 =$ the identity function, i.e., $f_0(m) = m$ for all $m \in \mathbb{N}$. Given $\sigma_n{}^\frown f_n \in [\mathbb{N}]^{\mathbb{N}}$, put $\sigma_{n+1} = \sigma_n{}^\frown\langle f_n(0)\rangle$ and recall that $f_n^{(1)}(m) = f_n(m+1)$ for all $m \in \mathbb{N}$; thus $\sigma_{n+1}{}^\frown f_n^{(1)} = \sigma_n{}^\frown f_n \in [\mathbb{N}]^{\mathbb{N}}$. By finitely many applications of $\Sigma^0_1$-RT in $M_1$, obtain $g_n \in M_1 \cap [\mathbb{N}]^{\mathbb{N}}$ such that, for all subsequences $\sigma$ of $\sigma_{n+1}$

and all $n_1, \dots, n_k \le n$,

$$(\forall h \in [\mathbb{N}]^{\mathbb{N}})\, \psi(n_1, \dots, n_k, \sigma^\frown(f_n^{(1)} \cdot g_n \cdot h)) \\ \vee (\forall h \in [\mathbb{N}]^{\mathbb{N}})\, \neg\psi(n_1, \dots, n_k, \sigma^\frown(f_n^{(1)} \cdot g_n \cdot h)).$$

Put $f_{n+1} = f_n^{(1)} \cdot g_n$. As part of the same recursion, define $p\colon \mathbb{N} \times \mathbb{N}^k \times [\mathbb{N}]^{<\mathbb{N}} \to \{0,1\}$ such that, for all $n$ and all subsequences $\sigma$ of $\sigma_{n+1}$ and $n_1, \dots, n_k \le n$,

$$p(n, n_1, \dots, n_k, \sigma) = \begin{cases} 1 & \text{if } (\forall h \in [\mathbb{N}]^{\mathbb{N}})\, \psi(n_1, \dots, n_k, \sigma^\frown(f_n^{(1)} \cdot g_n \cdot h)), \\ 0 & \text{if } (\forall h \in [\mathbb{N}]^{\mathbb{N}})\, \neg\psi(n_1, \dots, n_k, \sigma^\frown(f_n^{(1)} \cdot g_n \cdot h)). \end{cases}$$

Finally define $\widetilde{f} \in [\mathbb{N}]^{\mathbb{N}}$ by $\widetilde{f}(n) = f_n(0)$ for all $n \in \mathbb{N}$; thus $\widetilde{f}[n] = \sigma_n$ for all $n \in \mathbb{N}$. Note that $\widetilde{f} \in M_2$ and $p \in M_2$.

By construction we have

$$\psi(n_1, \dots, n_k, \widetilde{f} \cdot g) \leftrightarrow \exists n\, (p(n, n_1, \dots, n_k, (\widetilde{f} \cdot g)[n]) = 1)$$

and

$$\neg\psi(n_1, \dots, n_k, \widetilde{f} \cdot g) \leftrightarrow \exists n\, (p(n, n_1, \dots, n_k, (\widetilde{f} \cdot g)[n]) = 0),$$

for all $n_1, \dots, n_k \in \mathbb{N}$ and $g \in [\mathbb{N}]^{\mathbb{N}}$. Thus

$$\widetilde{\psi}(n_1, \dots, n_k, g) \equiv \psi(n_1, \dots, n_k, \widetilde{f} \cdot g)$$

is $\Delta^0_1$ with parameters in $M_2$. Hence

$$\begin{aligned} \widetilde{\varphi}(g) &\equiv \varphi(\widetilde{f} \cdot g) \\ &\equiv \exists n_1\, \forall n_2 \cdots n_k\, \psi(n_1, \dots, n_k, \widetilde{f} \cdot g) \\ &\equiv \exists n_1\, \forall n_2 \cdots n_k\, \widetilde{\psi}(n_1, \dots, n_k, g) \end{aligned}$$

is $\Sigma^0_k$ with parameters in $M_2$. Hence, by inductive hypothesis, there exists $h \in M_{k+1} \cap [\mathbb{N}]^{\mathbb{N}}$ such that $\forall g\, \widetilde{\varphi}(h \cdot g) \vee \forall g\, \neg\widetilde{\varphi}(h \cdot g)$, i.e., $\forall g\, \varphi(\widetilde{f} \cdot h \cdot g) \vee \forall g\, \neg\varphi(\widetilde{f} \cdot h \cdot g)$, where $g$ ranges over $[\mathbb{N}]^{\mathbb{N}}$. This completes the proof. □

Lemma VI.6.3. $\Pi^1_1$-CA$_0$ *proves* $\Sigma^0_\infty$-RT. *In other words, for each* $k \in \omega$, $\Pi^1_1$-CA$_0$ *proves* $\Sigma^0_k$-RT.

Proof. Let $\varphi(f)$ be a $\Sigma^0_k$ formula, $k \ge 1$. Reasoning in $\Pi^1_1$-CA$_0$, let $X \subseteq \mathbb{N}$ be such that all the parameters of $\varphi(f)$ are $\le_{\mathrm{T}} X$. By $k$ applications of theorem VII.2.10, we obtain countable coded $\beta$-models $X \in M_1 \in \cdots \in M_k$. Then lemma VI.6.2 gives $\exists h\, (\forall g\, \varphi(h \cdot g) \vee \forall g\, \neg\varphi(h \cdot g))$, i.e., $\Sigma^0_k$-RT for $\varphi(f)$. This proves the lemma. □

The main result of this section is:

Theorem VI.6.4. *The following are pairwise equivalent over* RCA$_0$:

1. $\Pi^1_1$ *comprehension*;
2. *the* $\Delta^0_2$ *Ramsey theorem*;
3. *the* $\Sigma^0_\infty$ *Ramsey theorem*.

Proof. This is immediate from lemmas VI.6.3 and VI.6.1. □

**Notes for §VI.6.** Lemma VI.6.1 is due to Simpson (unpublished notes, June 1981). Lemma VI.6.3 is related to results of Solovay [252]. See also Tanaka [262]. Related results are in §§III.7, V.9, VI.7.

## VI.7. Stronger Set Existence Axioms

We have seen (in §§V.8 and V.9) that $\mathsf{ATR}_0$ is just strong enough to prove $\Sigma^0_1$ determinacy and the $\Sigma^0_1$ Ramsey theorem. We have also seen (in §§VI.5 and VI.6) that $\Pi^1_1$-$\mathsf{CA}_0$ is just strong enough to prove $\Sigma^0_1 \wedge \Pi^1_1$ determinacy and the $\Sigma^0_\infty$ Ramsey theorem. The purpose of this section is to point out that stronger forms of determinacy and Ramsey's theorem require stronger set existence axioms.

In analogy with arithmetical transfinite recursion ($\mathsf{ATR}_0$, §V.2), the scheme of $\Pi^1_1$ transfinite recursion is defined as follows.

Definition VI.7.1 ($\Pi^1_1$ transfinite recursion). We define $\Pi^1_1$-$\mathsf{TR}_0$ to be the formal system consisting of $\mathsf{ACA}_0$ plus $\Pi^1_1$ *transfinite recursion*, i.e.,

$$\forall X\,(\mathrm{WO}(X) \to \exists Y\,\mathrm{H}_\theta(X, Y))$$

where $\theta$ is any $\Pi^1_1$ formula.

For $2 \le k < \infty$, the system $\Pi^1_k$-$\mathsf{TR}_0$ is defined similarly, with $\Pi^1_1$ replaced by $\Pi^1_k$.

Remark VI.7.2. Some results on models of $\Pi^1_1$-$\mathsf{TR}_0$ and related systems are in chapters VII and VIII.

Theorem VI.7.3. *The following are pairwise equivalent over* $\mathsf{RCA}_0$:

1. $\Pi^1_1$ *transfinite recursion*;
2. $\Delta^0_2$ *determinacy*;
3. *the* $\Delta^1_1$ *Ramsey theorem*.

Proof. We omit the proofs, which can be found in Tanaka [262, 263]. □

Remark VI.7.4. The previous theorem is due to Tanaka. In addition, Tanaka defined a stronger subsystem of $\mathsf{Z}_2$, $\Sigma^1_1$-$\mathsf{MI}_0$ (related to $\Sigma^1_1$ monotonic recursion and $\Sigma^1_1$ reflecting ordinals), and proved the following theorem.

Theorem VI.7.5. *The following are pairwise equivalent over* $\mathsf{RCA}_0$:

1. $\Sigma^1_1$-$\mathsf{MI}_0$;
2. $\Sigma^0_2$ *determinacy*;
3. *the* $\Sigma^1_1$ *Ramsey theorem*.

Proof. See Tanaka [262, 264]. □

Remark VI.7.6 (stronger forms of Ramsey's theorem). The Borel Ramsey theorem, i.e., the $\Delta^1_1$ Ramsey theorem, is also known as the Galvin/Prikry theorem; see Mathias [181] and Carlson/Simpson [33]. We have seen above that the Galvin/Prikry theorem and indeed the $\Sigma^1_1$ Ramsey theorem are provable in $\mathsf{Z}_2$. On the other hand, it is known that the $\Delta^1_2$ Ramsey theorem is not provable in ZFC. This follows from the fact that the canonical well ordering of $P(\omega)$ in $\mathrm{L}(X)$ is $\Sigma^1_2$ (definition VII.4.20, lemma VII.4.21, sublemma VII.6.8).

Remark VI.7.7 (stronger forms of determinacy). Friedman [66] has shown that $\Sigma^0_5$ determinacy is not provable in $\mathsf{Z}_2$. Martin [177, 178] has shown that Borel determinacy is provable in ZFC. Friedman [66, 71] has shown that the proof of Borel determinacy requires $\aleph_1$ applications of the power set axiom. Friedman [65] has shown that $\Sigma^1_1$ determinacy is not provable in ZFC; indeed, it is false in all forcing extensions of $\mathrm{L}(X)$. Harrington [104] has improved this by showing that $\Sigma^1_1$ determinacy is equivalent to $\forall X$ ($X^\#$ exists).

**Notes for §VI.7.** Theorems VI.7.3 and VI.7.5 are due to Tanaka [262, 263, 264]. A result along the lines of $1 \leftrightarrow 2$ of VI.7.3 was announced by Steel [256, page 24], but the proof has not been published. Regarding $1 \leftrightarrow 2$ of VI.7.5, see also Steel [256, pages 24–25] and Moschovakis [191, pages 414–415]. Regarding $1 \leftrightarrow 3$ of VI.7.5, see also Solovay [252]. For more on $\Sigma^1_1$ monotonic recursion and $\Sigma^1_1$ reflecting ordinals, see Richter/Aczel [206], Aanderaa [1], and Simpson [233].

## VI.8. Conclusions

In this chapter we have seen that several mathematical theorems are logically equivalent to $\Pi^1_1$-$\mathsf{CA}_0$. Among them are: the Cantor/Bendixson theorem for closed sets (§VI.1), Kondo's theorem on coanalytic uniformization (§VI.2), Silver's theorem on Borel equivalence relations (§VI.3), a key structure theorem for countable Abelian groups (§VI.4), the $\Delta^0_2$ Ramsey theorem (§VI.6), and $\Sigma^0_1 \wedge \Pi^0_1$ determinacy (§VI.5). We have also seen (§VI.7) that stronger forms of Ramsey's theorem and determinacy require stronger set existence axioms.

Our proof techniques in this chapter have been based mostly on the Kleene normal form theorem, via lemma VI.1.1 concerning paths through trees. We have also used an inner model technique (see lemmas VI.5.2 and VI.6.2) involving countable coded $\beta$-models (§VII.2).

# Part B

# MODELS OF SUBSYSTEMS OF $Z_2$

Chapter VII

# $\beta$-MODELS

A *$\beta$-model* is an $L_2$-model $M$ such that for all $\Sigma^1_1$ sentences $\varphi$ with parameters from $M$, $\varphi$ is true if and only if $M \models \varphi$. The purpose of this chapter is to study $\beta$-models of various subsystems of second order arithmetic. We concentrate on $\mathsf{ATR}_0$ and $\Pi^1_1$-$\mathsf{CA}_0$ and stronger systems. We make extensive use of set-theoretic methods.

Section VII.1 is introductory in nature. In it a recursion-theoretic result, the Kleene basis theorem, is used to obtain a description of the minimum $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$.

In §VII.2 we consider codes for countable $\beta$-models as defined *within* subsystems of $\mathsf{Z}_2$. We prove within $\Pi^1_1$-$\mathsf{CA}_0$ that for all $X$ there exists a countable coded $\beta$-model $M$ such that $X \in M$. We also study certain refinements of this result, involving a transfinite induction scheme.

In §§VII.3 and VII.4 we develop an apparatus whereby set-theoretic methods can be applied to the study of subsystems of $\mathsf{Z}_2$. To any $L_2$-theory $T_0 \supseteq \mathsf{ATR}_0$, we associate in §VII.3 a corresponding set-theoretic theory $T_0^{\mathrm{set}}$ in the language $L_{\mathrm{set}}$. We show that $T_0^{\mathrm{set}}$ proves the same $L_2$-sentences as $T_0$. In other words, $T_0^{\mathrm{set}}$ is a conservative extension of $T_0$. In §VII.4 we introduce constructible sets and show that their basic properties can be proved within $\mathsf{ATR}_0^{\mathrm{set}}$. We then go on to show that more advanced properties of constructible sets, e.g., the Shoenfield absoluteness theorem, can be proved within $\Pi^1_1$-$\mathsf{CA}_0^{\mathrm{set}}$.

The rest of the chapter employs the set-theoretic ideas of §§VII.3 and VII.4 to study $\beta$-models of the systems $\Pi^1_1$-$\mathsf{CA}_0$, $\Delta^1_2$-$\mathsf{CA}_0$, $\Pi^1_2$-$\mathsf{CA}_0$, $\Delta^1_3$-$\mathsf{CA}_0$, $\Pi^1_3$-$\mathsf{CA}_0$, ... . In §VII.5 we show that these systems have minimum $\beta$-models $\mathrm{M}^{\Pi}_1$, $\mathrm{M}^{\Delta}_2$, $\mathrm{M}^{\Pi}_2$, $\mathrm{M}^{\Delta}_3$, $\mathrm{M}^{\Pi}_3$, ... , which can be described in terms of initial segments of the constructible hierarchy. In §VII.6 we show that each of these minimum $\beta$-models satisfies an appropriate form of the axiom of choice. In §VII.7 we use reflection to show that these minimum $\beta$-models are all distinct.

Throughout this chapter, we formulate our results so as to apply not only to $\beta$-models but also to arbitrary models of the systems considered. Nevertheless, it will be clear that the methods are best adapted to the study of minimum $\beta$-models. Other methods will be developed in

chapters VIII and IX, in order to construct $\omega$-models and non-$\omega$-models, respectively.

## VII.1. The Minimum $\beta$-Model of $\Pi^1_1$-$\mathsf{CA}_0$

DEFINITION VII.1.1 ($\omega$-models). An *$\omega$-model* is an $L_2$-model $M$ such that the first order part of $M$ is the standard model $(\omega, +, \cdot, 0, 1, <)$ of $\mathsf{Z}_1$. We sometimes identify $M$ with the set $\mathcal{S}_M \subseteq P(\omega)$. Here $P(\omega)$ is the powerset of $\omega$.

DEFINITION VII.1.2 ($\beta$-models). A *$\beta$-model* is an $\omega$-model $M$ such that for any $\Sigma^1_1$ sentence $\varphi$ with parameters from $M$, $M \models \varphi$ if and only if $\varphi$ is true.

The purpose of this chapter is to study $\beta$-models of various subsystems of $\mathsf{Z}_2$. In the present introductory section, we study $\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$. We prove that there exists a *minimum* (i.e., unique smallest) $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$ (corollary VII.1.10). At the same time we obtain a characterization of $\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$ by means of the hyperjump (theorem VII.1.8). We also present a more general result which characterizes $\beta$-submodels of an arbitrary given model of $\Pi^1_1$-$\mathsf{CA}_0$ (definition VII.1.11, theorem VII.1.12).

Some of the ideas which are introduced here will be refined and generalized in later sections of this chapter. For instance, in §VII.5 we shall obtain an alternative description of the minimum $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$, by means of constructible sets.

Our first goal is to prove a formal version of a well known recursion-theoretic result known as the *Kleene basis theorem*. We begin with definitions of relative recursiveness and the hyperjump. For general background on recursion theory theory and hyperarithmetical theory, see for instance Kleene [142], Rogers [208], Shoenfield [222, chapters 6 and 7], and Sacks [211, part A].

DEFINITION VII.1.3 (universal lightface $\Pi^0_1$ formula). Let

$$\pi(e, m_1, \dots, m_i, X_1, \dots, X_j)$$

be a $\Pi^0_1$ formula with exactly the displayed free variables. (Here $m_1, \dots, m_i$ are free number variables, $X_1, \dots, X_j$ are free set variables, and $e$ is a distinguished free number variable.) We say that $\pi$ is *universal lightface* $\Pi^0_1$ if for all $\Pi^0_1$ formulas $\pi'$ with the same free variables as $\pi$, $\mathsf{RCA}_0$ proves

$$\forall e\, \exists e'\, \forall m_1 \cdots \forall X_1 \cdots (\pi(e', m_1, \dots, X_1, \dots) \leftrightarrow \pi'(e, m_1, \dots, X_1, \dots)).$$

It is known that for all numbers of variables $i, j < \omega$ there exists a universal lightface $\Pi^0_1$ formula. The existence of such formulas is closely related to the *enumeration theorem* in recursion theory.

Definition VII.1.4 (relative recursiveness). The following definition is made in $\mathsf{RCA}_0$. Let $\pi(e, m_1, X_1)$ be a fixed universal lightface $\Pi^0_1$ formula with exactly the displayed free variables. Given $X, Y \subseteq \mathbb{N}$ we say that $Y$ is *recursive in* $X$ or $X$*-recursive* (equivalently $Y$ *is Turing reducible to* $X$, written $Y \leq_{\mathrm{T}} X$), if there exist $e_0, e_1 \in \mathbb{N}$ such that for all $m$, $m \in Y \leftrightarrow \pi(e_1, m, X)$ and $m \notin Y \leftrightarrow \pi(e_0, m, X)$. In this case we say that $e = (e_0, e_1)$ is an $X$*-recursive index* of $Y$.

We say that $X$ *is Turing equivalent to* $Y$, written $X =_{\mathrm{T}} Y$, if $X \leq_{\mathrm{T}} Y$ and $Y \leq_{\mathrm{T}} X$. This is an equivalence relation on subsets of $\mathbb{N}$. A *Turing degree* is an $=_{\mathrm{T}}$-equivalence class.

Definition VII.1.5 (hyperjump). The following definition is made in $\mathsf{RCA}_0$. Let $f$ be a function variable, i.e., $f$ ranges over total functions $f : \mathbb{N} \to \mathbb{N}$. As usual we identify such a function with a set of ordered pairs $f \subseteq \mathbb{N} \times \mathbb{N} \subseteq \mathbb{N}$. Given $X \subseteq \mathbb{N}$, the *hyperjump of* $X$, denoted $\mathrm{HJ}(X)$, is the set of all $(m, e) \in \mathbb{N} \times \mathbb{N} \subseteq \mathbb{N}$ such that $\exists f\, \pi(e, m, f, X)$, if this set exists. Here $\pi(e, m_1, X_1, X_2)$ is a fixed universal lightface $\Pi^0_1$ formula with exactly the displayed free variables.

The next lemma is a formal version of the fact that $\mathrm{HJ}(X)$ is "complete" among sets which are lightface $\Sigma^1_1$ definable from $X$.

Lemma VII.1.6. *Let $\varphi(e, m, X)$ be a $\Sigma^1_1$ formula with only the displayed free variables. The following is provable in $\mathsf{ACA}_0$. For all $e \in \mathbb{N}$ and $X \subseteq \mathbb{N}$, if $\mathrm{HJ}(X)$ exists then $\{m : \varphi(e, m, X)\}$ exists and is recursive in $\mathrm{HJ}(X)$.*

Proof. By the proof of lemma V.1.4 (our formal version of the Kleene normal form theorem), we obtain a $\Pi^0_1$ formula

$$\pi'(e, m, f, X)$$

with only the displayed free variables such that $\mathsf{ACA}_0$ proves

$$\forall e\, \forall m\, \forall X\, (\varphi(e, m, X) \leftrightarrow \exists f\, \pi'(e, m, f, X)).$$

Now reasoning within $\mathsf{ACA}_0$, given $e$ let $e'$ be such that

$$\forall m\, \forall f\, \forall X\, (\pi(e', m, f, X) \leftrightarrow \pi'(e, m, f, X))$$

where $\pi$ is our fixed universal lightface $\Pi^0_1$ formula as in definition VII.1.5. Given $X$ such that $\mathrm{HJ}(X)$ exists, let $Y$ be the set of all $m$ such that $(m, e') \in \mathrm{HJ}(X)$. Clearly $Y \leq_{\mathrm{T}} \mathrm{HJ}(X)$ and $\forall m\, (m \in Y \leftrightarrow \varphi(e, m, X))$. This completes the proof. □

The following lemma is our formal version of the Kleene basis theorem.

Lemma VII.1.7 (formalized Kleene basis theorem). *Let $\varphi(m, Y, X)$ be a $\Sigma^1_1$ formula with only the displayed free variables. The following is provable in $\mathsf{ACA}_0$. Let $X \subseteq \mathbb{N}$ be given such that $\mathrm{HJ}(X)$ exists. For all $m$, if $\exists Y\, \varphi(m, Y, X)$ then $\exists Y\, (Y \leq_{\mathrm{T}} \mathrm{HJ}(X) \wedge \varphi(m, Y, X))$.*

PROOF. By the proof of lemma V.1.4, we obtain an arithmetical formula $\theta(m, \sigma, \tau, X)$ with only the displayed free variables, such that $\mathsf{ACA}_0$ proves

$$\forall m\, \forall X\, \forall Y\, (\varphi(m, Y, X) \leftrightarrow \exists f\, \forall n\, \theta(m, Y[n], f[n], X)).$$

Now reasoning within $\mathsf{ACA}_0$, let $X$ be given such that $\mathrm{HJ}(X)$ exists. Let $G$ be the set of all $(m, \sigma, \tau) \in \mathbb{N} \times 2^{<\mathbb{N}} \times \mathbb{N}^{<\mathbb{N}}$ such that

$$\exists Y\, \exists f\, (\forall n\, \theta(m, Y[n], f[n], X) \wedge Y[\mathrm{lh}(\sigma)] = \sigma \wedge f[\mathrm{lh}(\tau)] = \tau).$$

By lemma VII.1.6, $G$ exists and is recursive in $\mathrm{HJ}(X)$. Now let $m$ be given such that $\exists Y\, \varphi(m, Y, X)$. Then clearly $(m, \langle\rangle, \langle\rangle) \in G$. Define $Y(n)$ and $f(n)$ by recursion on $n$ as follows: $Y(n) = 1$ if $(m, Y[n]^\frown\langle 1\rangle, f[n]) \in G$; $Y(n) = 0$ otherwise; $f(n) =$ least $j$ such that $(m, Y[n+1], f[n]^\frown\langle j\rangle) \in G$. Clearly $Y$ and $f$ are recursive in $G$ and, by $\Delta^0_1$ induction, $(m, Y[n], f[n]) \in G$ for all $n \in \mathbb{N}$. In particular $\forall n\, \theta(m, Y[n], f[n], X)$ so $\varphi(m, Y, X)$ holds. Also $Y \leq_{\mathrm{T}} \mathrm{HJ}(X)$ by transitivity of $\leq_{\mathrm{T}}$, since $Y \leq_{\mathrm{T}} G$ and $G \leq_{\mathrm{T}} \mathrm{HJ}(X)$. This completes the proof. □

It can also be shown that lemmas VII.1.6 and VII.1.7 are provable in $\mathsf{RCA}_0$ (rather than $\mathsf{ACA}_0$).

We are now ready to present the following characterization of $\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$.

THEOREM VII.1.8 ($\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$). *Let $M$ be an $\omega$-model of $\mathsf{RCA}_0$. The following are equivalent.*

1. *$M$ is a $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$.*
2. *$M$ is closed under hyperjump, i.e., $\mathrm{HJ}(X) \in M$ for all $X \in M$.*

PROOF. Suppose first that $M$ is a $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$. Let $\pi$ be $\Pi^0_1$ as in the definition of hyperjump (definition VII.1.5). Given $X \in M$, by $\Sigma^1_1$ comprehension within $M$ let $Y \in M$ be the set of all $(m, e)$ such that $M \models \exists f\, \pi(e, m, f, X)$. Since $M$ is a $\beta$-model, we have $M \models \exists f\, \pi(e, m, f, X)$ if and only if $\exists f\, \pi(e, m, f, X)$ is true, for all $e$ and $m$. Hence $Y = \mathrm{HJ}(X)$. Hence $\mathrm{HJ}(X) \in M$. This proves that 1 implies 2.

For the converse, let $M$ be an $\omega$-model of $\mathsf{RCA}_0$ which is closed under hyperjump. We must show that $M$ is a $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$. Let $\varphi(m)$ be $\Sigma^1_1$ with no free variables other than $m$, but with parameters from $M$. Let $X \in M$ be such that all of the parameters of $\varphi(m)$ are recursive in $X$. Thus $\varphi(m)$ can be written as $\exists Y\, \theta(m, Y, X)$ where $\theta(m, Y, X)$ is arithmetical with no free variables other than $m$ and $Y$, and no parameters other than $X$. By assumption $\mathrm{HJ}(X) \in M$. Hence $Y \in M$ for all $Y \leq_{\mathrm{T}} \mathrm{HJ}(X)$. Hence by the Kleene basis theorem VII.1.7, we see that for each $m$, $M \models \exists Y\, \theta(m, Y, X)$ if and only if $\exists Y\, \theta(m, Y, X)$ is true. In other words, $M \models \varphi(m)$ if and only if $\varphi(m)$ is true. This shows that $M$ is a $\beta$-model. Furthermore, by lemma VII.1.6, the set $Z = \{m : \varphi(m) \text{ is true}\}$ is recursive in $\mathrm{HJ}(X)$. Hence $Z \in M$ and $M \models \forall m\, (m \in Z \leftrightarrow \varphi(m))$. Thus $M \models \Sigma^1_1$ comprehension, or equivalently $\Pi^1_1$ comprehension. The proof is complete. □

We now define iterated hyperjumps $\mathrm{HJ}(n, X)$, $n \in \omega$ by recursion on $n$ as follows: $\mathrm{HJ}(0, X) = X$ and $\mathrm{HJ}(n+1, X) = \mathrm{HJ}(\mathrm{HJ}(n, X))$.

Corollary VII.1.9. *Given $X \subseteq \omega$, there exists a minimum (i.e., unique smallest) $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$ containing $X$. This model can be characterized as the $\omega$-model consisting of all sets $Y \subseteq \omega$ such that $Y \leq_{\mathrm{T}} \mathrm{HJ}(n, X)$ for some $n \in \omega$.*

Corollary VII.1.10. *There exists a minimum $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$. It consists of all sets $X \subseteq \omega$ such that $X$ is recursive in $\mathrm{HJ}(n, \emptyset)$ for some $n \in \omega$.*

We shall see in chapter VIII that $\Pi^1_1$-$\mathsf{CA}_0$ does not have a minimum (or even a minimal) $\omega$-model.

We now generalize the previous theorem so as to apply to $\beta$-submodels of a given model $M'$ which need not be a $\beta$-model.

Definition VII.1.11 ($\beta$-submodels). Let $M$ and $M'$ be $\mathrm{L}_2$-models. We say that *$M$ is an $\omega$-submodel of $M'$*, written $M \subseteq_\omega M'$, if $M$ is a submodel of $M'$ and has the same first order part as $M'$. We say that *$M$ is a $\beta$-submodel of $M'$*, written $M \subseteq_\beta M'$, if $M \subseteq_\omega M'$ and, for all $\Sigma^1_1$ sentences $\varphi$ with parameters from $M$, $M \models \varphi$ if and only if $M' \models \varphi$.

Thus a $\beta$-model is the same thing as a $\beta$-submodel of the standard or intended model $(\omega, P(\omega), +, \cdot, 0, 1, <)$ of $\mathsf{Z}_2$. But in general, the $M$ and $M'$ in the above definition need not be $\beta$-models or even $\omega$-models.

Theorem VII.1.12. *Let $M$ and $M'$ be given such that $M \subseteq_\omega M'$, $M' \models \Pi^1_1$-$\mathsf{CA}_0$, and $M \models \mathsf{RCA}_0$. The following are equivalent.*

1. *$M \subseteq_\beta M'$ and $M \models \Pi^1_1$-$\mathsf{CA}_0$.*
2. *$M$ is closed under the $M'$-hyperjump, i.e., for all $X \in M$ there exists $Y \in M$ such that $M' \models (Y \text{ is the hyperjump of } X)$.*

Proof. This is a straightforward generalization of theorem VII.1.8. □

Corollary VII.1.13. *Let $X \in M' \models \Pi^1_1$-$\mathsf{CA}_0$ be given. Among all $\beta$-submodels $M \subseteq_\beta M'$ such that $X \in M \models \Pi^1_1$-$\mathsf{CA}_0$, there exists a unique smallest one. It consists of all $Y \in M'$ such that $M' \models Y \leq_{\mathrm{T}} \mathrm{HJ}(n, X)$ for some $n \in \omega$.*

Corollary VII.1.14. *Let $M' \models \Pi^1_1$-$\mathsf{CA}_0$ be given. Among all $M \subseteq_\beta M'$ such that $M \models \Pi^1_1$-$\mathsf{CA}_0$, there exists a unique smallest one. It consists of all $X \in M'$ such that $M' \models X \leq_{\mathrm{T}} \mathrm{HJ}(n, \emptyset)$ for some $n \in \omega$.*

In the two previous corollaries, note that the restriction $n \in \omega$ applies even if $M'$ is not an $\omega$-model.

Exercise VII.1.15. Let $M$ be an $\omega$-model of $\mathsf{RCA}_0$. Show that if $\mathrm{HJ}(X) \in M$, then $X \in M$ and $\mathrm{HJ}(X)$ is satisfied in $M$ to be the hyperjump of $X$. Generalize this so as to apply to $\omega$-submodels of a given model.

EXERCISE VII.1.16. Show that $\Pi^1_1$-$\mathsf{CA}_0$ is equivalent over $\mathsf{RCA}_0$ to the assertion that for all $X$, $\mathrm{HJ}(X)$ exists.

EXERCISE VII.1.17. Recall from §VI.7 that $\Pi^1_1$-$\mathsf{TR}_0$ consists of $\mathsf{RCA}_0$ plus all axioms $\forall Y\,(\mathrm{WO}(Y) \to \exists Z\,\mathrm{H}_\theta(Y,Z))$ where $\theta(n,Z)$ is any $\Pi^1_1$ formula. Show that $\Pi^1_1$-$\mathsf{TR}_0$ is equivalent over $\mathsf{RCA}_0$ to the assertion that $\forall X\,\forall Y\,(\mathrm{WO}(Y) \to$ the hyperjump can be iterated along $Y$ starting with $X)$.

EXERCISE VII.1.18. Give a characterization of $\beta$-models of $\Pi^1_1$-$\mathsf{TR}_0$ analogous to theorem VII.1.8. Prove that there exists a minimum $\beta$-model of $\Pi^1_1$-$\mathsf{TR}_0$. Prove that for any model of $\Pi^1_1$-$\mathsf{TR}_0$ there is a smallest $\beta$-submodel of $\Pi^1_1$-$\mathsf{TR}_0$.

It is natural to ask whether there exists a minimum $\beta$-model of $\mathsf{ATR}_0$. This question is answered negatively by the following result, which will be proved in chapter VIII; see corollary VIII.6.9.

THEOREM VII.1.19. *Let $M'$ be any countable model of $\mathsf{ATR}_0$. Then there exists a proper $\beta$-submodel $M \subsetneq_\beta M'$, $M \neq M'$. For any such $M$ we have also $M \models \mathsf{ATR}_0$.*

COROLLARY VII.1.20. *There is no minimum $\beta$-model of $\mathsf{ATR}_0$.*

EXERCISE VII.1.21. Show that any $\beta$-model is a model of $\mathsf{ATR}_0$. More generally, show that if $M \subseteq_\beta M'$ and $M' \models \mathsf{ATR}_0$, then $M \models \mathsf{ATR}_0$.

Further results on $\beta$-models of $\mathsf{ATR}_0$ will be presented in §VII.2 and in chapter VIII. Further results on $\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$ and stronger theories will be presented in §§VII.5, VII.6 and VII.7.

**Notes for §VII.1.** The Kleene basis theorem is due to Kleene [143]. Our characterization of $\beta$-models of $\Pi^1_1$-$\mathsf{CA}_0$ in terms of $\leq_{\mathrm{T}}$ and HJ (theorem VII.1.8) is well known. A set-theoretic characterization of such models is given in exercise VII.3.36. The minimum $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$ can also be described in terms of constructible sets; see theorem VII.5.17.

## VII.2. Countable Coded $\beta$-Models

In this section we consider countable $\beta$-models which are encoded as single subsets of $\mathbb{N}$. We show that $\Pi^1_1$-$\mathsf{CA}_0$ is strong enough to prove the existence of such models. We also study a formal theory of transfinite induction which is satisfied by all such models.

We begin by giving a definition within $\mathsf{RCA}_0$ of codes for countable $\omega$-models together with the appropriate satisfaction concept. Recall that any set $X \subseteq \mathbb{N}$ can be viewed as a code for a countable sequence of sets $\langle (X)_n : n \in \mathbb{N}\rangle$ where $(X)_n = \{i : (i,n) \in X\}$.

Definition VII.2.1 (countable coded $\omega$-models). The following definition is made within $\mathsf{RCA}_0$. A *countable coded $\omega$-model* is a set $W \subseteq \mathbb{N}$, viewed as encoding the $\mathrm{L}_2$-model

$$M = (\mathbb{N}, \mathcal{S}_M, +, \cdot, 0, 1, <)$$

with

$$\mathcal{S}_M = \{(W)_n : n \in \mathbb{N}\}.$$

Let $\mathrm{Snt}_M$ be the set of (Gödel numbers of) sentences of $L_2$ with parameters from $|M| \cup \mathcal{S}_M$, i.e., from $\mathbb{N} \cup \{(W)_n : n \in \mathbb{N}\}$. Given $\varphi \in \mathrm{Snt}_M$, let $\mathrm{Sub}_M(\varphi)$ be the set of $\psi \in \mathrm{Snt}_M$ such that $\psi$ is a substitution instance of a subformula of $\varphi$. A *valuation for* $\varphi$ is a function $f : \mathrm{Sub}_M(\varphi) \to \{0, 1\}$ which obeys the following clauses:

$$f(t_1 = t_2) = \begin{cases} 1 & \text{if } t_1 = t_2, \\ 0 & \text{if } t_1 \neq t_2; \end{cases}$$

$$f(t_1 < t_2) = \begin{cases} 1 & \text{if } t_1 < t_2, \\ 0 & \text{if } t_1 \geq t_2; \end{cases}$$

$$f(\neg\psi) = 1 - f(\psi);$$

$$f(\psi_1 \wedge \psi_2) = \begin{cases} 1 & \text{if } f(\psi_1) = f(\psi_2) = 1, \\ 0 & \text{otherwise;} \end{cases}$$

$$f(\forall m\, \psi(m)) = \begin{cases} 1 & \text{if } f(\psi(m)) = 1 \text{ for all } m \in \mathbb{N}, \\ 0 & \text{otherwise;} \end{cases}$$

$$f(\forall X\, \psi(X)) = \begin{cases} 1 & \text{if } f(\psi((W)_n)) = 1 \text{ for all } n \in \mathbb{N}, \\ 0 & \text{otherwise.} \end{cases}$$

Clearly for any $\varphi \in \mathrm{Snt}_M$ there is at most one such valuation. We say that $M$ *satisfies* $\varphi$, written $M \models \varphi$, if there exists a valuation $f$ for $\varphi$ such that $f(\varphi) = 1$. (This concept of satisfaction is similar to the notion of weak model which was introduced in §II.8.)

Lemma VII.2.2. *Let $\varphi$ be any sentence of* $\mathrm{L}_2$. *Then* $\mathsf{ACA}_0$ *proves the following. For all countable coded $\omega$-models $M$ there exists a unique valuation $f : \mathrm{Sub}_M(\varphi) \to \{0, 1\}$.*

Proof. The proof is straightforward by arithmetical comprehension using the code of $M$ as a parameter. □

Fix a universal lightface $\Pi^0_1$ formula $\pi(e, m_1, m_2, X_1, X_2, X_3)$ with exactly the displayed free variables (definition VII.1.3). Let $\varphi_1(e, m, X, Y)$ be the $\Sigma^1_1$ formula

$$\exists Z\, \forall n\, \neg\pi(e, m, n, X, Y, Z).$$

Thus $\varphi_1(e, m, X, Y)$ is in some sense a universal lightface $\Sigma^1_1$ formula with free variables $e, m, X, Y$.

DEFINITION VII.2.3 (countable coded $\beta$-models). A *countable coded $\beta$-model* is defined in $\mathsf{RCA}_0$ to be a countable coded $\omega$-model $M$ such that for all $e, m \in \mathbb{N}$ and $X, Y \in \mathcal{S}_M$, $\varphi_1(e, m, X, Y)$ if and only if $M \models \varphi_1(e, m, X, Y)$.

The following lemma will be superseded by theorem VII.2.7.

LEMMA VII.2.4. *It is provable in* $\mathsf{ACA}_0$ *that, for any countable coded $\beta$-model $M$, we have* $M \models \mathsf{ACA}_0$.

PROOF. $\mathsf{ACA}_0$ is axiomatized by finitely many $\Pi^1_1$ sentences plus the sentence

$$\forall e\, \forall m\, \forall X\, \forall Y\, \exists Z\, \forall n\, (n \in Z \leftrightarrow \pi(e, m, n, X, Y, Y)) \tag{18}$$

where $\pi$ is as above. It suffices to show that $\mathsf{ACA}_0$ proves that all countable coded $\beta$-models satisfy (18). Reasoning in $\mathsf{ACA}_0$, let $M$ be a countable coded $\beta$-model and let $e, m \in \mathbb{N}$ and $X, Y \in \mathcal{S}_M$ be given. Let $e'$ be such that

$$\forall X_1\, \forall X_2\, \forall X_3\, (\forall n\, \neg\pi(e', m, n, X_1, X_2, X_3) \leftrightarrow \forall n\, (n \in X_1 \leftrightarrow \pi(e, m, n, X_2, X_3, X_3))).$$

By arithmetical comprehension we have

$$\exists Z\, \forall n\, (n \in Z \leftrightarrow \pi(e, m, n, X, Y, Y)).$$

Hence $\varphi_1(e', m, X, Y)$ holds. Hence

$$M \models \varphi_1(e', m, X, Y).$$

Hence $M \models \exists Z\, \forall n\, (n \in Z \leftrightarrow \pi(e, m, n, X, Y, Y))$. This completes the proof. □

DEFINITION VII.2.5 ($A\Pi^1_1$ formulas). $A\Pi^1_1$ is the smallest class of $\mathrm{L}_2$-formulas which contains all $\Sigma^1_1$ formulas and is closed under number quantifiers and propositional connectives. (The notation $A\Pi^1_1$ stands for *arithmetical-in-*$\Pi^1_1$.)

LEMMA VII.2.6. *Let $\varphi(m_1, \ldots, m_i, X_1, \ldots, X_j)$ be an $A\Pi^1_1$ formula with exactly the displayed free variables. Then* $\mathsf{ACA}_0$ *proves the following. For all countable coded $\beta$-models $M$ and $m_1, \ldots, m_i \in \mathbb{N}$ and $X_1, \ldots, X_j \in \mathcal{S}_M$, $\varphi(m_1, \ldots, m_i, X_1, \ldots, X_j)$ if and only if $M \models \varphi(m_1, \ldots, m_i, X_1, \ldots, X_j)$.*

PROOF. First assume that $\varphi$ is $\Sigma^1_1$. Let $e < \omega$ be such that $\mathsf{ACA}_0$ proves

$$\forall m_1 \cdots \forall m_i\, \forall X_1 \cdots \forall X_j\, (\varphi(m_1, \ldots, m_i, X_1, \ldots, X_j) \leftrightarrow \varphi_1(e, \langle m_1, \ldots, m_i\rangle, X_1 \oplus \cdots \oplus X_j, \emptyset)).$$

Then the desired conclusion follows easily from definition VII.2.3 and lemma VII.2.4. The result for arbitrary $A\Pi^1_1$ formulas $\varphi$ follows by a straightforward induction on the complexity of $\varphi$. □

We shall now prove (within $\mathsf{ACA}_0$) that every countable $\beta$-model is a model of $\mathsf{ATR}_0$.

Theorem VII.2.7. *For any countable coded $\beta$-model $M$, we have $M \models \mathsf{ATR}_0$. This fact is provable in* $\mathsf{ACA}_0$.

Proof. We reason in $\mathsf{ACA}_0$. Let $M$ be a countable coded $\beta$-model. By lemma VII.2.4 we have $M \models \mathsf{ACA}_0$. Let $\theta(n, Y)$ be any arithmetical formula with parameters in $M$. We must show that $M \models \forall X\,(\mathrm{WO}(X) \rightarrow \exists Y\,\mathrm{H}_\theta(X, Y))$ (see §V.2.). Let $X \in M$ be such that $M \models \mathrm{WO}(X)$. By lemma VII.2.6 we have $\mathrm{WO}(X)$. Letting $W$ be a code for $M$, we claim that for each $j \in \mathrm{field}(X)$ there exists $m$ such that $\mathrm{H}_\theta(j, X, (W)_m)$ (see definitions VII.2.1 and V.2.2). This claim will now be proved by arithmetical transfinite induction along $X$ (lemma V.2.1). Suppose $j \in \mathrm{field}(X)$ and $\forall i(i <_X j \rightarrow \exists m\,\mathrm{H}_\theta(i, X, (W)_m))$. By arithmetical comprehension let

$$Z = \{(n, i) \colon i <_X j \wedge \theta(n, (W)_{f(i)})\}$$

where $f(i) = $ least $m$ such that $\mathrm{H}_\theta(i, X, (W)_m)$. Thus we have $\mathrm{H}_\theta(j, X, Z)$. Since $M$ is a $\beta$-model, it follows by lemma VII.2.6 that $M \models \exists Y\,\mathrm{H}_\theta(j, X, Y)$. In other words, $\mathrm{H}_\theta(j, X, (W)_m)$ for some $m$. This proves the claim. Now by arithmetical comprehension let

$$Z = \{(n, j) \colon j \in \mathrm{field}(X) \wedge \theta(n, (W)_{f(j)})\}$$

where $f(j) = $ least $m$ such that $\mathrm{H}_\theta(j, X, (W)_m)$. Thus we have $\mathrm{H}_\theta(X, Z)$. Since $M$ is a $\beta$-model, it follows by lemma VII.2.6 that $M \models \exists Y\,\mathrm{H}_\theta(X, Y)$. This completes the proof. □

Corollary VII.2.8. $\mathsf{ATR}_0$ *does not prove the existence of a countable coded $\beta$-model.*

Proof. Suppose that $\mathsf{ATR}_0$ proves the existence of a countable $\beta$-model. By theorem VII.2.7 it follows that $\mathsf{ATR}_0$ proves the consistency of $\mathsf{ATR}_0$. This contradicts Gödel's second incompleteness theorem [94, 115, 55, 222]. □

We shall now show that the existence of countable coded $\beta$-models is provable in $\Pi^1_1$-$\mathsf{CA}_0$. Recall from definition VII.1.5 that the hyperjump of $X$ is denoted $\mathrm{HJ}(X)$.

Lemma VII.2.9. *The following is provable in* $\mathsf{ACA}_0$. *For all $X \subseteq \mathbb{N}$, $\mathrm{HJ}(X)$ exists if and only if there exists a countable coded $\beta$-model $M$ such that $X \in M$.*

Proof. We reason in $\mathsf{ACA}_0$. Suppose first that $X \in M$ for some countable coded $\beta$-model $M$. Let $W$ be a code for $M$ (definition VII.2.1). Let $\pi(e, m, f, X)$ be $\Pi^0_1$ as in the definition of hyperjump. By arithmetical

comprehension using $W$ as a parameter, let $Y$ be the set of $(e,m)$ such that $\exists n\,((W)_n$ is a total function from $\mathbb{N}$ into $\mathbb{N}$ such that $\pi(e,m,(W)_n,X)$ holds). Thus $Y=\{(e,m)\colon M\models\exists f\,\pi(e,m,f,X)\}$. Since $M$ is a $\beta$-model, it follows by lemma VII.2.6 and the definition of hyperjump that $Y=\{(e,m)\colon \exists f\,\pi(e,m,f,X)\}=\mathrm{HJ}(X)$. This proves the easy direction of the lemma.

We now prove the hard direction. Suppose that $\mathrm{HJ}(X)$ exists. Let

$$\pi(e,m_1,X_1,X_2,X_3)$$

be a universal lightface $\Pi^0_1$ formula with exactly the displayed free variables (definition VII.1.3). Write $\pi^*(n,h,g)$ as an abbreviation for $\forall e\,\forall m\,(n=(e,m)\to\pi(e,m,X,h,g))$. We are going to define a function $f\colon\mathbb{N}\to\mathbb{N}$, $f\leq_{\mathrm{T}}\mathrm{HJ}(X)$, such that

$$\forall n\,\forall g\,(\pi^*(n,(f)^n,g)\to\pi^*(n,(f)^n,(f)_n)) \tag{19}$$

where $(f)_n\colon\mathbb{N}\to\mathbb{N}$ and $(f)^n\colon\mathbb{N}\to\mathbb{N}$ are given by

$$(f)_n(i)=f((n,i)),$$

$$(f)^n(j)=\begin{cases} f(j) & \text{if } j=(m,i) \text{ for some } m<n \text{ and } i\leq j,\\ 0 & \text{otherwise.}\end{cases}$$

Suppose for a moment that this $f$ has been found. Set $W=\{(i,n)\colon f((n,i))=1\}$. Let $M$ be the countable $\omega$-model which is encoded by $W$ (definition VII.2.1). We claim that $X\in M$ and that $M$ is a $\beta$-model. To see that $X\in M$, let $n_0$ be such that

$$\forall g\,\forall h\,(\pi^*(n_0,h,g)\leftrightarrow\forall i\,(g(i)=1\leftrightarrow i\in X)).$$

Then clearly $(W)_{n_0}=X$ so $X\in M$. To see that $M$ is a $\beta$-model, let $e,m\in\mathbb{N}$ and $Y_1,Y_2\in\mathcal{S}_M$ be given such that $\varphi_1(e,m,Y_1,Y_2)$ holds. We must show that $M\models\varphi_1(e,m,Y_1,Y_2)$. Write $\varphi_1(e,m,Y_1,Y_2)$ as

$$\exists Z\,\forall m_1\,\exists m_2\,\theta(e,m,m_1,m_2,Y_1,Y_2,Z)$$

where $\theta$ is $\Sigma^0_0$ with exactly the displayed free variables. Fix $n_1$ and $n_2$ such that $(W)_{n_1}=Y_1$ and $(W)_{n_2}=Y_2$. Let $n_3>\max(n_1,n_2)$ be such that, for all $g$ and all $h$, $\pi^*(n_3,h,g)$ if and only if

$$\forall m_1\,\theta(e,m,m_1,(g)_0(m_1),\{i\colon(h)_{n_1}(i)=1\},\{i\colon(h)_{n_2}(i)=1\},\{i\colon(g)_1(i)=1\})$$

holds. Then clearly

$$\forall m_1\,\exists m_2\,\theta(e,m,m_1,m_2,Y_1,Y_2,\{i\colon((f)_{n_3})_1(i)=1\})$$

holds. Let $n_4>n_3$ be such that

$$\forall h\,\forall g\,(\pi^*(n_4,h,g)\leftrightarrow g=((h)_{e_1})_1).$$

Then clearly $(f)_{n_4} = ((f)_{e_1})_1$, hence $\forall m_1 \exists m_2\ \theta(e, m, m_1, m_2, Y_1, Y_2, (W)_{n_4})$ holds. Thus $M \models \varphi_1(e, m, Y_1, Y_2)$. This shows that $M$ is a $\beta$-model.

It remains to find $f \leq_T \mathrm{HJ}(X)$ satisfying (19). We shall construct $f$ by finite approximations, as in the proof of the Kleene basis theorem (lemma VII.1.7). Let $G$ be the set of $(\sigma, \tau) \in 2^{<\mathbb{N}} \times \mathbb{N}^{<\mathbb{N}}$ such that

$$\exists h\,(h[\mathrm{lh}(\tau)] = \tau \wedge \forall n\,((n < \mathrm{lh}(\sigma) \wedge \sigma(n) = 1) \to \pi^*(n, (h)^n, (h)_n))).$$

By lemma VII.1.6, $G$ exists and is recursive in $\mathrm{HJ}(X)$. Clearly $(\langle\rangle, \langle\rangle) \in G$. Furthermore, if $(\sigma, \tau) \in G$ then $(\sigma^\frown\langle 0\rangle, \tau) \in G$ and also $(\sigma, \tau^\frown\langle j\rangle) \in G$ for at least one $j \in \mathbb{N}$. Recursively in $G$ define $s\colon \mathbb{N} \to \{0, 1\}$ and $f\colon \mathbb{N} \to \mathbb{N}$ as follows: $s(n) = 1$ if $(s[n]^\frown\langle 1\rangle, f[n]) \in G$; $s(n) = 0$ otherwise; $f(n) =$ least $j$ such that $(s[n+1], f[n]^\frown\langle j\rangle) \in G$. By $\Delta^0_1$ induction, $(s[n], f[n]) \in G$ for all $n$. Now having defined $f$, we claim that (19) holds. Let $n$ be given. If $s(n) = 1$, then by construction we have

$$\forall m \exists h\,(h[m] = f[m] \wedge \pi^*(n, (h)^n, (h)_n)),$$

hence $\pi^*(n, (f)^n, (f)_n)$. If $s(n) = 0$, then by construction

$$\neg\exists g\,\pi^*(n, (f)^n, g).$$

(We used here the fact that $(n, i) \geq n$ for all $i$.) In either case we get (19).

This completes the proof of lemma VII.2.9. □

The following theorem says that $\Pi^1_1$ comprehension is equivalent to the existence of "sufficiently many" countable coded $\beta$-models.

THEOREM VII.2.10 (existence of countable coded $\beta$-models). *$\Pi^1_1$-$\mathsf{CA}_0$ is equivalent over $\mathsf{ACA}_0$ to the following statement. For all $X$ there exists a countable coded $\beta$-model $M$ such that $X \in M$.*

PROOF. This follows immediately from lemmas VII.1.6 and VII.2.9. □

COROLLARY VII.2.11. *There exists a $\beta$-model of $\mathsf{ATR}_0$ which is not a model of $\Pi^1_1$-$\mathsf{CA}_0$.*

PROOF. By corollary VII.1.10 let $M'$ be the minimum $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$. By theorem VII.2.10 let $W \in M'$ be such that $M' \models (W$ is a code for a countable $\beta$-model). Let $M$ be the countable $\beta$-model of which $W$ is a code. Then clearly $M \subseteq_\beta M'$ and $M \neq M'$. Hence $M$ is not a model of $\Pi^1_1$-$\mathsf{CA}_0$. By theorem VII.2.7, $M \models \mathsf{ATR}_0$. This completes the proof. □

We can sharpen the previous corollary as follows:

COROLLARY VII.2.12. *Given $X \subseteq \omega$, there exists a countable $\beta$-model $M$ such that $X \in M$ and, for all $Y \in M$, $\mathrm{HJ}(Y) \leq_T \mathrm{HJ}(X)$. In particular $\mathrm{HJ}(X) \notin M$ so $M$ is not closed under hyperjump. Hence $M$ is not a model of $\Pi^1_1$-$\mathsf{CA}_0$.*

PROOF. Given $X$, let $M$ be the countable $\beta$-model which was constructed in the proof of lemma VII.2.9. Thus $X \in M$. Let $f$ and $s$ be as in that construction. Then for all $n$, we have $s(n) = 1$ if and only if

$\exists g\, \pi^*(n, (f)^n, g)$. Since $s \leq_T \mathrm{HJ}(X)$, it follows that $\mathrm{HJ}(Y) \leq_T \mathrm{HJ}(X)$ for all $Y \in M$. Since $\mathrm{HJ}(\mathrm{HJ}(X)) \not\leq_T \mathrm{HJ}(X)$, it follows that $\mathrm{HJ}(X) \notin M$. By theorem VII.1.8 it follows that $M$ is not a model of $\Pi^1_1$-$\mathsf{CA}_0$. □

COROLLARY VII.2.13. *There exists a countable $\beta$-model $M$ such that* $M \models$ (there is no countable coded $\beta$-model).

PROOF. By the previous corollary, let $M$ be a countable $\beta$-model such that $\mathrm{HJ}(\emptyset) \notin M$. By lemma VII.2.9, it follows that $M \models$ (there is no countable coded $\beta$-model). □

We shall now introduce a formal theory of transfinite induction along arbitrary countable well orderings with respect to arbitrary formulas of $\mathrm{L}_2$.

DEFINITION VII.2.14 (transfinite induction). Recall from §V.1 the $\Pi^1_1$ formula $\mathrm{WO}(X)$, which says that $X$ is a (code for a) countable well ordering. Given an $\mathrm{L}_2$-formula $\psi(j)$ with a distinguished free number variable $j$, let $\mathrm{TI}(X, \psi)$ be the formula

$$\forall j\, (\forall i\, (i <_X j \to \psi(i)) \to \psi(j)) \to \forall j\, \psi(j)$$

expressing induction along $X$ with respect to $\psi$. For $0 \leq k < \omega$ we define $\Pi^1_k$-$\mathsf{TI}_0$ to be the subsystem of $\mathsf{Z}_2$ whose axioms are those of $\mathsf{ACA}_0$ plus the scheme of $\Pi^1_k$ *transfinite induction*:

$$\forall X\, (\mathrm{WO}(X) \to \mathrm{TI}(X, \psi))$$

where $\psi(j)$ is any $\Pi^1_k$ formula. We define $\Sigma^1_k$-$\mathsf{TI}_0$ similarly. We also set

$$\Pi^1_\infty\text{-}\mathsf{TI}_0 = \bigcup_{k \in \omega} \Pi^1_k\text{-}\mathsf{TI}_0.$$

It is easy to see that any $\beta$-model is a model of $\Pi^1_\infty$-$\mathsf{TI}_0$. The following lemma expresses two formal versions of this observation.

LEMMA VII.2.15 ($\beta$-models and $\Pi^1_\infty$-$\mathsf{TI}_0$).

1. *For each $k < \omega$, $\mathsf{ACA}_0$ proves that all countable coded $\beta$-models satisfy $\Pi^1_k$-$\mathsf{TI}_0$.*
2. *$\mathsf{ATR}_0$ proves that all countable coded $\beta$-models satisfy $\Pi^1_\infty$-$\mathsf{TI}_0$.*

PROOF. For part 1 we reason in $\mathsf{ACA}_0$. Let $M$ be a countable coded $\beta$-model. By lemma VII.2.4 we have $M \models \mathsf{ACA}_0$. Suppose that $X \in M$ and $M \models \mathrm{WO}(X)$. Given an $\mathrm{L}_2$-formula $\psi(j)$ with parameters from $M$, we must show that $M \models \mathrm{TI}(X, \psi)$. Suppose that $M \models \forall j\, (\forall i\, (i <_X j \to \psi(i)) \to \psi(j))$. By lemma VII.2.2 let $f : \mathrm{Sub}_M(\forall j\, \psi(j)) \to \{0, 1\}$ be a valuation for $\forall j\, \psi(j)$. Put $Y = \{j : f(\psi(j)) = 1\}$. Thus we have $\forall j\, (\forall i\, (i <_X j \to i \in Y) \to j \in Y)$. Since $M \models \mathrm{WO}(X)$, it follows by lemma VII.2.6 that $\mathrm{WO}(X)$ is true. Hence $Y = \mathbb{N}$. Hence $f(\forall j\, \psi(j)) = 1$, i.e., $M \models \forall j\, \psi(j)$. Thus $M \models \mathrm{TI}(X, \psi)$. We have now shown that, for each $\mathrm{L}_2$-formula $\psi$, $\mathsf{ACA}_0$ proves that every countable coded $\beta$-model satisfies $\forall X\, (\mathrm{WO}(X) \to \mathrm{TI}(X, \psi))$. Taking $\psi$ to be a universal $\Pi^1_k$ formula, we obtain part 1.

For part 2 we reason in $\mathsf{ATR}_0$. Let $M$ be a countable coded $\beta$-model. By arithmetical transfinite recursion, there exists a total valuation $f : \mathrm{Snt}_M \to \{0,1\}$. As in the proof of part 1, we can show that $f(\varphi) = 1$ for all $\varphi \in \mathrm{Snt}_M$ of the form $\forall X\,(\mathrm{WO}(X) \to \mathrm{TI}(X,\psi))$. Thus $M \models \Pi^1_\infty\text{-}\mathsf{TI}_0$. (We used arithmetical transfinite recursion only to prove the existence of the valuation $f$. For this we did need not the full strength of $\mathsf{ATR}_0$. Rather we needed only a single arithmetical recursion along $\mathbb{N}$ using the code of $M$ as a parameter.) □

Theorem VII.2.16. $\Pi^1_1\text{-}\mathsf{CA}_0$ *proves the existence of a countable coded* $\beta$*-model of* $\Pi^1_\infty\text{-}\mathsf{TI}_0$.

Proof. By theorem VII.2.10, $\Pi^1_1\text{-}\mathsf{CA}_0$ proves the existence of a countable coded $\beta$-model. Since $\Pi^1_1\text{-}\mathsf{CA}_0 \supseteq \mathsf{ATR}_0$, lemma VII.2.15.2 applies to show that any such model satisfies $\Pi^1_\infty\text{-}\mathsf{TI}_0$. □

Our next goal is to obtain a sort of weak converse to the previous theorem.

Lemma VII.2.17. *Let* $M$ *be any model of* $\Pi^1_\infty\text{-}\mathsf{TI}_0$. *Then there exists a model* $M'$ *such that* $M \subseteq_\beta M' \models \mathsf{ACA}_0$ *and, for all* $Y \in M$, $M' \models \mathrm{HJ}(Y)$ *exists.*

Proof. Let $M'$ be the model with the same first order part as $M$ and $\mathcal{S}_{M'} = \mathrm{Def}(M) =$ the set of all $Z \subseteq |M|$ such that $Z$ is definable over $M$ allowing parameters from $M$. Clearly $M \subseteq_\omega M'$ and $M' \models \mathsf{ACA}_0$. Since $M \models \Pi^1_\infty\text{-}\mathsf{TI}_0$, we have

$$M \models \mathrm{WO}(X) \quad \text{if and only if} \quad M' \models \mathrm{WO}(X)$$

for all $X \in M$. To show that $M \subseteq_\beta M'$, let $\varphi$ be any $\Sigma^1_1$ sentence with parameters from $M$. By the Kleene normal form theorem (lemma V.1.4), let $\theta(\tau)$ be arithmetical with the same parameters as $\varphi$ and such that $\mathsf{ACA}_0$ proves $\varphi \leftrightarrow \exists f\,\forall n\,\theta(f[n])$. Let $T \in M$ be the tree of unsecured sequences, i.e.,

$$M \models \forall \tau\,(\tau \in T \leftrightarrow \forall n\,(n \le \mathrm{lh}(\tau) \to \theta(\tau[n]))).$$

Then by lemma V.1.3 we have

$$\begin{aligned}
&M \models \varphi && \text{if and only if}\\
&M \models T \text{ has a path}, && \text{if and only if}\\
&M \models \neg\mathrm{WO}(\mathrm{KB}(T)), && \text{if and only if}\\
&M' \models \neg\mathrm{WO}(\mathrm{KB}(T)), && \text{if and only if}\\
&M' \models T \text{ has a path}, && \text{if and only if}\\
&M' \models \varphi.
\end{aligned}$$

Thus $M \subseteq_\beta M'$. Now given $Y \in M$, set

$$Z = \{(e,m) \colon M \models \exists f\,\pi(e,m,f,Y)\}$$

where $\pi$ is universal lightface $\Pi^0_1$ as in the definition of hyperjump (definition VII.1.5). Thus $Z \in M'$ and, since $M \subseteq_\beta M'$, $M' \models Z = \mathrm{HJ}(Y)$. This completes the proof. □

THEOREM VII.2.18. *Let $\varphi(X)$ be an $A\Pi^1_1$ formula with no free variables other than $X$. The following assertions are pairwise equivalent.*

1. $\Pi^1_\infty$-$\mathsf{TI}_0$ *proves* $\forall X \varphi(X)$.
2. $\mathsf{ACA}_0$ *proves* $\forall X$ (*if* $\mathrm{HJ}(X)$ *exists then* $\varphi(X)$ *holds*).
3. $\mathsf{ACA}_0$ *proves that all countable coded $\beta$-models satisfy* $\forall X\, \varphi(X)$.

PROOF. The equivalence of 2 and 3 follows from lemmas VII.2.6 and VII.2.9. Suppose now that 1 holds, i.e., $\Pi^1_\infty$-$\mathsf{TI}_0$ proves $\forall X\, \varphi(X)$. Then, for some $k < \omega$, $\Pi^1_k$-$\mathsf{TI}_0$ proves $\forall X\, \varphi(X)$. By lemma VII.2.15.1, $\mathsf{ACA}_0$ proves that all countable coded $\beta$-models satisfy $\Pi^1_k$-$\mathsf{TI}_0$. Hence $\mathsf{ACA}_0$ proves that all such models satisfy $\forall X\, \varphi(X)$. This is assertion 3. Thus 1 implies 3.

It remains to show that 2 implies 1. Assume 2. Given $M \models \Pi^1_\infty$-$\mathsf{TI}_0$, let $M'$ be as in lemma VII.2.17. For any $X \in M$ we have $M' \models \mathrm{HJ}(X)$ exists. Hence by assumption $M' \models \varphi(X)$. Since $M \subseteq_\beta M'$, it follows as in lemma VII.2.6 that $M \models \varphi(X)$. Thus $M \models \forall X\, \varphi(X)$. This shows that any model of $\Pi^1_\infty$-$\mathsf{TI}_0$ satisfies $\forall X\, \varphi(X)$. Hence by Gödel's completeness theorem, $\Pi^1_\infty$-$\mathsf{TI}_0$ proves $\forall X\, \varphi(X)$. This completes the proof of theorem VII.2.18. □

As an application we note:

COROLLARY VII.2.19. $\mathsf{ATR}_0$ *is provable from* $\Pi^1_\infty$-$\mathsf{TI}_0$.

PROOF. $\mathsf{ATR}_0$ is axiomatized by $\mathsf{ACA}_0$ plus a certain $\Pi^1_2$ sentence $\forall X\, \varphi(X)$, where $\varphi(X)$ is $\Sigma^1_1$. By theorem VII.2.7, $\mathsf{ACA}_0$ proves that $\forall X\, \varphi(X)$ holds in every countable coded $\beta$-model. By theorem VII.2.18 it follows that $\Pi^1_\infty$-$\mathsf{TI}_0$ proves $\forall X\, \varphi(X)$. □

REMARK VII.2.20. It can be shown that $\mathsf{ATR}_0$ is provable from $\Sigma^1_1$-$\mathsf{TI}_0$. In fact, $\Sigma^1_1$-$\mathsf{TI}_0$ is equivalent to $\mathsf{ATR}_0$ plus $\Sigma^1_1$-$\mathsf{IND}$ (definition VII.6.1.2 below). The systems $\Pi^1_1$-$\mathsf{TI}_0$ and $\Sigma^1_1$-$\mathsf{TI}_0$ will be discussed in chapter VIII. See also Simpson [235].

We now draw some further corollaries.

COROLLARY VII.2.21. *Let $\varphi$ be an $A\Pi^1_1$ sentence. The following assertions are pairwise equivalent.*

1. *$\varphi$ is provable in* $\Pi^1_\infty$-$\mathsf{TI}_0$.
2. *$\varphi$ is provable in* $\mathsf{ACA}_0$ *assuming the existence of* $\mathrm{HJ}(\emptyset)$.
3. *It is provable in* $\mathsf{ACA}_0$ *that every countable coded $\beta$-model satisfies $\varphi$.*

PROOF. This is immediate from theorem VII.2.18. □

COROLLARY VII.2.22. *For each $k < \omega$, $\Pi^1_\infty$-$\mathsf{TI}_0$ proves the existence of a countable coded $\omega$-model of $\Pi^1_k$-$\mathsf{TI}_0$.*

Proof. Let $\varphi_k$ be the $\Sigma^1_1$ sentence which asserts the existence of a countable coded $\omega$-model of $\Pi^1_k$-$\mathsf{TI}_0$. By lemmas VII.2.9 and VII.2.15.1, $\mathsf{ACA}_0$ proves that if $\mathrm{HJ}(\emptyset)$ exists then $\varphi_k$ holds. Hence by corollary VII.2.21, $\Pi^1_\infty$-$\mathsf{TI}_0$ proves $\varphi_k$. □

Corollary VII.2.23. $\Pi^1_\infty$-$\mathsf{TI}_0$ *is not finitely axiomatizable.*

Proof. If it were, it would be equivalent to one of the finitely axiomatizable theories $\Pi^1_k$-$\mathsf{TI}_0$, $k < \omega$. Hence by corollary VII.2.22 and theorem II.8.8 (our formal version of the soundness theorem), $\Pi^1_k$-$\mathsf{TI}_0$ would prove its own consistency. This would contradict Gödel's second incompleteness theorem [94, 115, 55, 222]. □

Remark VII.2.24. Later (§VIII.5) we shall prove the following result. Let $T_0$ be any finitely axiomatizable $\mathrm{L}_2$-theory. Suppose there exists a countable $\omega$-model of $T_0$. Then there exists a countable $\omega$-model of $T_0$ which is not a model of $\Pi^1_\infty$-$\mathsf{TI}_0$. This will provide an alternative proof that $\Pi^1_\infty$-$\mathsf{TI}_0$ is not finitely axiomatizable.

We end this section with some further results, stated as exercises.

Exercise VII.2.25. Let $A\Pi^1_1$-$\mathsf{TI}_0$ be the $\mathrm{L}_2$-theory consisting of $\mathsf{ACA}_0$ plus the scheme $\forall X\,(\mathrm{WO}(X) \to \mathrm{TI}(X, \varphi))$ for all $A\Pi^1_1$ formulas $\varphi$. Thus $A\Pi^1_1$-$\mathsf{TI}_0$ is a subsystem of $\Pi^1_\infty$-$\mathsf{TI}_0$. Show that $A\Pi^1_1$-$\mathsf{TI}_0$ proves the same $\Pi^1_2$ sentences as $\Pi^1_\infty$-$\mathsf{TI}_0$. Show that lemma VII.2.17, theorem VII.2.18, and corollaries VII.2.19, VII.2.21, and VII.2.22 continue to hold with $\Pi^1_\infty$-$\mathsf{TI}_0$ weakened to $A\Pi^1_1$-$\mathsf{TI}_0$. Show that $A\Pi^1_1$-$\mathsf{TI}_0$ is not finitely axiomatizable.

Exercise VII.2.26. Show that lemma VII.2.4, theorem VII.2.7, lemma VII.2.9, and theorem VII.2.10 can be proved in $\mathsf{RCA}_0$ (rather than $\mathsf{ACA}_0$).

Exercise VII.2.27. Show that $\mathsf{RCA}_0$ proves that all countable coded $\beta$-models satisfy $\Pi^1_2$-$\mathsf{TI}_0$. (This is a variant of lemma VII.2.15.1.)

For the next few exercises, we need the following definition.

Definition VII.2.28. $R\Sigma^1_1$ is the class of $\Sigma^1_1$ formulas of the form $\exists X\,\psi$ where $\psi$ is $\Pi^0_2$. ($R\Sigma^1_1$ stands for *restricted*-$\Sigma^1_1$.) We say that $M$ is a *restricted-$\beta$-submodel of $M'$*, written $M \subseteq_{R\beta} M'$, if $M \subseteq_\omega M'$ and for all $R\Sigma^1_1$ sentences $\varphi$ with parameters from $M$, $M \models \varphi$ if and only if $M' \models \varphi$. Let $AR\Pi^1_1$ be the smallest class of $L_2$ formulas which includes $R\Sigma^1_1$ and is closed under number quantifiers and propositional connectives. ($AR\Pi^1_1$ stands for *arithmetical-in-restricted*-$\Pi^1_1$.)

Exercise VII.2.29. Show that lemma VII.2.6 remains true if $\mathsf{ACA}_0$, $A\Pi^1_1$ are replaced by $\mathsf{RCA}_0$, $AR\Pi^1_1$ respectively.

Exercise VII.2.30. Let $M$ be any model of $\Pi^1_2$-$\mathsf{TI}_0$. Show that there exists a model $M'$ such that $M \subseteq_{R\beta} M' \models \mathsf{RCA}_0$ and, for all $Y \in M$, $M' \models \mathrm{HJ}(Y)$ exists. (This is a variant of lemma VII.2.17.)

EXERCISE VII.2.31. Prove the following variant of theorem VII.2.18. Let $\varphi(X)$ be an $AR\Pi^1_1$ formula with no free variables other than $X$. The following assertions are pairwise equivalent.

1. $\Pi^1_2$-$\mathsf{TI}_0$ proves $\forall X\, \varphi(X)$.
2. $\mathsf{RCA}_0$ proves $\forall X$ (if $\mathsf{HJ}(X)$ exists then $\varphi(X)$ holds).
3. $\mathsf{RCA}_0$ proves that all countable coded $\beta$-models satisfy $\forall X\, \varphi(X)$.

EXERCISE VII.2.32. Show that $\Pi^1_2$-$\mathsf{TI}_0$ proves $\forall X\, \exists M$ ($M$ is countable coded $\omega$-model of $\mathsf{ATR}_0$ and $X \in M$).

**Notes for §VII.2.** The main results of this section are essentially due to Friedman [63]. The notion of $A\Pi^1_1$ formula and theorem VII.2.18 and the results stated as exercises VII.2.25–VII.2.32 are due to Simpson (unpublished notes, 1985). Theorem VII.2.18 and exercise VII.2.31 have been applied in Blass/Hirst/Simpson [21] to show that certain combinatorial theorems are provable in $\Pi^1_2$-$\mathsf{TI}_0$.

## VII.3. A Set-Theoretic Interpretation of $\mathsf{ATR}_0$

There is a certain resemblance between (i) $\beta$-models for the language of second order arithmetic, and (ii) transitive models for the language of set theory. The purpose of this section is to explicate this resemblance.

Our main result is that there exists a close, precise relationship of mutual interpretability between (i) $\mathsf{ATR}_0$ and (ii) a certain finitely axiomatizable system of set theory known as $\mathsf{ATR}^{\mathrm{set}}_0$. This result will be used in §VII.4 to show that certain set-theoretic constructions can be carried out "within $\mathsf{ATR}_0$" (actually within $\mathsf{ATR}^{\mathrm{set}}_0$). Then in §§VII.5, VII.6, and VII.7 those constructions will be applied to study $\beta$-models of certain strong subsystems of $\mathsf{Z}_2$, and to prove conservation results for those subsystems.

DEFINITION VII.3.1. The *set-theoretic language*, $\mathrm{L}_{\mathrm{set}}$, is the one-sorted, first order language with two binary relation symbols $\in$ and $=$. In addition, $\mathrm{L}_{\mathrm{set}}$ contains propositional connectives $\wedge$, $\vee$, $\neg$, $\rightarrow$, $\leftrightarrow$, quantifiers $\forall$, $\exists$, and *set-theoretic variables* $v_i$, $i \in \omega$.

The set-theoretic variables $v_0, v_1, \ldots, v_i, \ldots$ are intended to range over *sets* in the sense of Zermelo/Fraenkel set theory. Thus $v_i \in v_j$ means that $v_i$ is an element of $v_j$, while $v_i = v_j$ means that $v_i$ and $v_j$ are equal, i.e., have the same elements.

NOTATION. In writing formulas of $\mathrm{L}_{\mathrm{set}}$, we shall employ the following notational conventions.

1. We use $u, v, w, x, y, z, \ldots$ as metavariables standing for set-theoretic variables $v_i$, $i \in \omega$. In any given context, it is assumed that $u, v, w, x, y, z, \ldots$ stand for distinct set-theoretic variables.
2. $u \notin v$, $u \neq v$ are abbreviations for $\neg u \in v$, $\neg u = v$ respectively.

3. $\emptyset$ = the empty set = the unique set $u$ such that $\forall x\,(x \notin u)$. (We shall have axioms which imply the existence and uniqueness of $\emptyset$.)
4. $\{x\colon \varphi(x)\}$ = the unique set $u$ such that $\forall x\,(x \in u \leftrightarrow \varphi(x))$, if such a set $u$ exists; $\{x\colon \varphi(x)\} = \emptyset$ otherwise. Here $\varphi(x)$ is any formula of $\mathrm{L}_{\mathrm{set}}$, and $u$ is a variable which does not occur freely in $\varphi$. Thus $\{x\colon \varphi(x)\}$ behaves as a *term*. If $\varphi(x)$ has free variables other than $x$, then the term $\{x\colon \varphi(x)\}$ also has those free variables. The set (denoted by the term) $\{x\colon \varphi(x)\}$ is said to *exist properly* if $\exists u\,\forall x\,(x \in u \leftrightarrow \varphi(x))$.
5. $\{t\colon \varphi\} = \{y\colon \exists x_1 \cdots \exists x_n\,(y = t \wedge \varphi)\}$. Here $t$ is any term, $\varphi$ is any formula, $y$ is a variable which does not occur freely in $t$ or $\varphi$, and $x_1, \ldots, x_n$ are exactly the variables which do occur freely in $t$.

DEFINITION VII.3.2 (abbreviated terms). Within $\mathrm{L}_{\mathrm{set}}$ we use the following abbreviated terms.

1. $\bigcup u = \{y\colon \exists x\,(y \in x \wedge x \in u)\}$ (union).
2. $\{u, v\} = \{x\colon x = u \vee x = v\}$ (unordered pair).
3. $u - v = \{x\colon x \in u \wedge x \notin v\}$ (complement).
4. $u \cap v = u - (u - v)$ (intersection).
5. $u \cup v = \bigcup\{u, v\}$ (union).
6. $\{x\} = \{x, x\}$ (singleton).
7. $\langle y, x\rangle = \{\{y, x\}, \{x\}\}$ (ordered pair).
8. $v \times u = \{\langle y, x\rangle\colon y \in v \wedge x \in u\}$ (Cartesian product).
9. $\mathrm{dom}(w) = \{x\colon \exists y\,(\langle y, x\rangle \in w)\}$ (domain).
10. $\mathrm{rng}(w) = \{y\colon \exists x\,(\langle y, x\rangle \in w)\}$ (range).
11. $\mathrm{field}(w) = \mathrm{dom}(w) \cup \mathrm{rng}(w)$ (field).
12. $w^{-1} = \{\langle x, y\rangle\colon \langle y, x\rangle \in w\}$ (inverse).
13. $w'x$ = the unique $y$ such that $\langle y, x\rangle \in w$, if such a $y$ exists; $w'x = \emptyset$ otherwise (value of $w$ at $x$).
14. $w \restriction u = w \cap (\mathrm{rng}(w) \times u)$ (restriction).
15. $w''u = \mathrm{rng}(w \restriction u)$ (range of the restriction).
16. $\in \restriction u = \{\langle y, x\rangle\colon y \in x \wedge x \in u\}$.

DEFINITION VII.3.3. $\mathsf{B}_0^{\mathrm{set}}$ is a finitely axiomatized theory in the language $\mathrm{L}_{\mathrm{set}}$. The four axioms of $\mathsf{B}_0^{\mathrm{set}}$ are as follows.

1. Axiom of Equality: $\forall u\,\forall v\,\forall w\,(u = u \wedge (u = v \to v = u) \wedge ((u = v \wedge v = w) \to u = w) \wedge ((u = v \wedge v \in w) \to u \in w) \wedge ((u \in v \wedge v = w) \to u \in w))$.
2. Axiom of Extensionality: $\forall u\,\forall v\,(\forall x\,(x \in u \leftrightarrow x \in v) \to u = v)$.
3. Axiom of Infinity: $\exists u\,(\emptyset \in u \wedge \forall x\,\forall y\,((x \in u \wedge y \in u) \to x \cup \{y\} \in u)$.
4. Axiom of Rudimentary Closure: We have an axiom which asserts, for all $u$, $v$ and $w$, the proper existence of $\{u, v\}$, $u - v$, $u \times v$, $\bigcup u$,

$\in\restriction u$, $\mathrm{dom}(w)$, $w^{-1}$, and

$$\{\langle y,\langle x,z\rangle\rangle\colon \langle y,x\rangle\in w\wedge z\in u\},$$
$$\{\langle y,\langle z,x\rangle\rangle\colon \langle y,x\rangle\in w\wedge z\in u\},$$
$$\{v\colon \exists x\,(x\in u\wedge v=w''\{x\})\}.$$

DEFINITION VII.3.4 ($\Sigma^{\mathrm{set}}_k$ formulas). The class of $\Delta^{\mathrm{set}}_0$ formulas of $\mathrm{L}_{\mathrm{set}}$ is defined inductively as follows. The formulas $u=v$, $u\neq v$, $u\in v$, $u\notin v$ are $\Delta^{\mathrm{set}}_0$. If $\varphi$ and $\psi$ are $\Delta^{\mathrm{set}}_0$ then so are $\varphi\wedge\psi$ and $\varphi\vee\psi$. If $\varphi$ is $\Delta^{\mathrm{set}}_0$ then so are $\forall u\,(u\in v\to\varphi)$ and $\exists u\,(u\in v\wedge\varphi)$. The quantifiers $\forall u\,(u\in v\to\cdots)$ and $\exists u\,(u\in v\wedge\cdots)$ are known as *bounded set-theoretic quantifiers*.

For $k<\omega$, a formula of $\mathrm{L}_{\mathrm{set}}$ is called $\Sigma^{\mathrm{set}}_k$ (respectively $\Pi^{\mathrm{set}}_k$ formula) if it is of the form $\exists u_1\,\forall u_2\cdots u_k\,\varphi$ (respectively $\forall u_1\,\exists u_2\cdots u_k\,\varphi$) where $\varphi$ is $\Delta^{\mathrm{set}}_0$. (This hierarchy of formulas will play an important role in §VII.5.)

LEMMA VII.3.5 ($\Delta^{\mathrm{set}}_0$ comprehension). *The scheme of* $\Delta^{\mathrm{set}}_0$ comprehension *is provable in* $\mathsf{B}^{\mathrm{set}}_0$. *In other words,* $\mathsf{B}^{\mathrm{set}}_0$ *proves*

$$\forall u\,\exists v\,\forall x\,(x\in v\leftrightarrow(x\in u\wedge\varphi(x)))$$

*where* $\varphi(x)$ *is any* $\Delta^{\mathrm{set}}_0$ *formula and* $v$ *is a variable which does not ocur freely in* $\varphi(x)$.

PROOF. See Jensen [131, §1]. Alternatively, change the definition of $\mathsf{B}^{\mathrm{set}}_0$ so as to include the $\Delta^{\mathrm{set}}_0$ comprehension scheme. (It is not then obvious that $\mathsf{B}^{\mathrm{set}}_0$ is finitely axiomatizable. However, this will not matter.) □

DEFINITION VII.3.6 (abbreviated formulas). Within $\mathsf{B}^{\mathrm{set}}_0$ we use the following abbreviated formulas.

1. $u\subseteq v\leftrightarrow u$ is a *subset* of $v$, i.e., $\forall x\,(x\in u\to x\in v)$.
2. $\mathrm{Rel}(r)\leftrightarrow r$ is a *relation*, i.e., $r\subseteq\mathrm{rng}(r)\times\mathrm{dom}(r)$.
3. $\mathrm{Fcn}(f)\leftrightarrow f$ is a *function*, i.e., $\mathrm{Rel}(f)\wedge\forall x\,\forall y\,\forall z\,((\langle y,x\rangle\in f\wedge\langle z,x\rangle\in f)\to y=z)$.
4. $\mathrm{Inj}(f)\leftrightarrow f$ is an *injection*, i.e., $\mathrm{Fcn}(f)\wedge\forall x\,\forall y\,\forall z\,((\langle z,x\rangle\in f\wedge\langle z,y\rangle\in f)\to x=y)$.
5. $u\approx v\leftrightarrow u$ and $v$ are *equinumerous*, i.e., $\exists f\,(\mathrm{Inj}(f)\wedge\mathrm{dom}(f)=u\wedge\mathrm{rng}(f)=v)$.
6. $\mathrm{Trans}(u)\leftrightarrow u$ is *transitive*, i.e., $\forall x\,\forall y\,((x\in y\wedge y\in u)\to x\in u)$.
7. $\mathrm{Ord}(u)\leftrightarrow u$ is an *ordinal*, i.e., $\mathrm{Trans}(u)\wedge\forall x\,\forall y\,((x\in u\wedge y\in u)\to(x\in y\vee x=y\vee y\in x))\wedge\forall v\,((v\subseteq u\wedge v\neq\emptyset)\to\exists x\,(x\in v\wedge\forall y\,(y\in v\to y\notin x)))$.
8. $\mathrm{Succ}(u)\leftrightarrow u$ is a *successor ordinal*, i.e., $\mathrm{Ord}(u)\wedge\exists v\,(u=v\cup\{v\})$.
9. $\mathrm{Lim}(u)\leftrightarrow u$ is a *limit ordinal*, i.e., $\mathrm{Ord}(u)\wedge u\neq\emptyset\wedge\neg\mathrm{Succ}(u)$.
10. $\mathrm{FinOrd}(u)\leftrightarrow u$ is a *finite ordinal*, i.e., $\mathrm{Ord}(u)\wedge\forall v\,(v\in u\cup\{u\}\to(v=\emptyset\vee\mathrm{Succ}(v)))$.
11. $\mathrm{Fin}(u)\leftrightarrow u$ is *finite*, i.e., $\exists v\,(u\approx v\wedge\mathrm{FinOrd}(v))$.
12. $\mathrm{HFin}(u)\leftrightarrow u$ is *hereditarily finite*, i.e., $\exists v\,(u\subseteq v\wedge\mathrm{Trans}(v)\wedge\mathrm{Fin}(v))$.

13. $\mathrm{Ctbl}(u) \leftrightarrow u$ is *countable*, i.e., $\exists f\,(\mathrm{Inj}(f) \wedge \mathrm{dom}(f) = u \wedge \forall y\,(y \in \mathrm{rng}(f) \rightarrow \mathrm{FinOrd}(y)))$.
14. $\mathrm{HCtbl}(u) \leftrightarrow u$ is *hereditarily countable*, i.e., $\exists v\,(u \subseteq v \wedge \mathrm{Trans}(v) \wedge \mathrm{Ctbl}(v))$.

We use $\alpha, \beta, \gamma, \delta, \ldots$ as special variables ranging over ordinals. We use $i, j, k, m, n, \ldots$ as special variables ranging over finite ordinals. We write $0 = \emptyset$, $1 = \{0\}$, $2 = \{0, 1\}$, $\ldots$; $\alpha + 1 = \alpha \cup \{\alpha\}$; $\alpha < \beta \leftrightarrow \alpha \in \beta$; $\alpha \leq \beta \leftrightarrow (\alpha < \beta \vee \alpha = \beta)$; $\omega = \{m : \mathrm{FinOrd}(m)\}$; $\mathrm{HF} = \{u : \mathrm{HFin}(u)\}$.

LEMMA VII.3.7. *The following facts are provable in* $\mathsf{B}_0^{\mathrm{set}}$.

1. $\neg\alpha < \alpha$; $\alpha = \{\beta : \beta < \alpha\}$.
2. $(\alpha < \beta \wedge \beta < \gamma) \rightarrow \alpha < \gamma$.
3. $\alpha < \beta \vee \alpha = \beta \vee \beta < \alpha$.
4. $\mathrm{Ord}(\alpha + 1)$; $\forall\beta\,(\beta < \alpha + 1 \leftrightarrow \beta \leq \alpha)$.
5. $(\mathrm{Lim}(\beta) \wedge \alpha < \beta) \rightarrow \alpha + 1 < \beta$.
6. $\mathrm{Lim}(\omega)$; $\forall\alpha\,(\alpha < \omega \leftrightarrow \mathrm{Fin}(\alpha))$.
7. *Let $z$ be a nonempty set of ordinals. Then*: (i) *$z$ has a least element*; (ii) *$\bigcup z$ is an ordinal*; (iii) *$\bigcup z$ is the least upper bound of $z$*.
8. $u \approx u$; $u \approx v \rightarrow v \approx u$; $(u \approx v \wedge v \approx w) \rightarrow u \approx w$.
9. $\emptyset \approx 0$; $(u \approx m \wedge x \notin u) \rightarrow u \cup \{x\} \approx m + 1$.
10. $(u \approx m \wedge v \approx n \wedge u \subseteq v) \rightarrow m \leq n$.
11. $m \approx n \leftrightarrow m = n$.
12. $\mathrm{Fin}(u) \leftrightarrow \exists m\,(u \approx m)$.
13. $\mathrm{Fin}(\emptyset)$; $\mathrm{Fin}(x) \rightarrow \mathrm{Fin}(x \cup \{y\})$.
14. $(u \subseteq v \wedge \mathrm{Fin}(v)) \rightarrow \mathrm{Fin}(u)$.
15. $(\mathrm{Fin}(u) \wedge \mathrm{Fin}(v)) \rightarrow (\mathrm{Fin}(u \cup v) \wedge \mathrm{Fin}(u \times v))$.
16. $(\mathrm{Fin}(u) \wedge \forall v\,(v \in u \rightarrow \mathrm{Fin}(v))) \rightarrow \mathrm{Fin}(\bigcup u)$.
17. $(\forall v\,(v \in w \rightarrow v \subseteq u) \wedge \mathrm{Trans}(u)) \rightarrow \mathrm{Trans}(u \cup w)$.
18. *The set* $\mathrm{HF} = \{u : \mathrm{HFin}(u)\}$ *exists properly.*
19. $u \in \mathrm{HF} \leftrightarrow (\mathrm{Fin}(u) \wedge u \subseteq \mathrm{HF})$.

PROOF. The proof is straightforward using lemma VII.3.5. □

We are now ready to define the theory $\mathsf{ATR}_0^{\mathrm{set}}$.

DEFINITION VII.3.8. $\mathsf{ATR}_0^{\mathrm{set}}$ is a finitely axiomatized theory in the set-theoretic language $\mathrm{L}_{\mathrm{set}}$. The axioms of $\mathsf{ATR}_0^{\mathrm{set}}$ are those of $\mathsf{B}_0^{\mathrm{set}}$ plus the following three:

1. Axiom of Regularity:
$$\forall u\,(u \neq \emptyset \rightarrow \exists x\,(x \in u \wedge \forall y\,(y \in u \rightarrow y \notin x))).$$
2. Axiom of Countability: $\forall u\,(u$ is hereditarily countable$)$.
3. Axiom Beta: A relation $r$ is said to be *regular* if
$$\forall u\,(u \neq \emptyset \rightarrow \exists x\,(x \in u \wedge \forall y\,(y \in u \rightarrow \langle y, x\rangle \notin r))).$$
The axiom asserts that, for all regular relations $r$, there exists a function $f$ such that $\mathrm{dom}(f) = \mathrm{field}(r)$ and, for all $x \in \mathrm{field}(r)$,

$f'x = f''\{y: \langle y, x\rangle \in r\}$. This $f$ is called the *collapsing function* of $r$.

It can be shown (in ZF, for instance) that the hereditarily countable sets form a transitive model of $\mathsf{ATR}_0^{\mathrm{set}}$.

We shall see that there is a canonical one-to-one correspondence between transitive models of $\mathsf{ATR}_0^{\mathrm{set}}$ and $\beta$-models of $\mathsf{ATR}_0$. This is a special case of a more general canonical one-to-one correspondence between arbitrary models of $\mathsf{ATR}_0^{\mathrm{set}}$ and arbitrary models of $\mathsf{ATR}_0$. We now give one direction of the more general correspondence.

THEOREM VII.3.9. *Each axiom of* $\mathsf{ATR}_0$ *is, in its natural translation, a theorem of* $\mathsf{ATR}_0^{\mathrm{set}}$.

PROOF. The *natural translation* of $L_2$ into $L_{\mathrm{set}}$ is defined as follows. Then number variables of $L_2$ are interpreted in $L_{\mathrm{set}}$ as ranging over finite ordinals, i.e., elements of $\omega$. The set variables of $L_2$ are interpreted in $L_{\mathrm{set}}$ as ranging over subsets of $\omega$. Using lemma VII.3.5 and parts 11, 12 and 15 of lemma VII.3.7, $\mathsf{B}_0^{\mathrm{set}}$ proves the existence of functions $+, \cdot$ with $\mathrm{dom}(+) = \mathrm{dom}(\cdot) = \omega \times \omega$ where $m + n =$ the unique $k \in \omega$ such that $(m \times \{0\}) \cup (n \times \{1\}) \approx k$, $m \cdot n =$ the unique $k \in \omega$ such that $m \times n \approx k$. The symbols $+, \cdot, 0, 1, <, =, \in$ of $L_2$ are then interpreted by means of their obvious counterparts over $\omega$ in $L_{\mathrm{set}}$. By lemmas VII.3.5 and VII.3.7 it is clear that each axiom of $\mathsf{ACA}_0$ becomes, under the above translation, a theorem of $\mathsf{B}_0^{\mathrm{set}}$.

Without comment, we shall from now on identify formulas of $L_2$ with their translations into $L_{\mathrm{set}}$ as given above.

It remains to show that the principal axiom of $\mathsf{ATR}_0$ is a theorem of $\mathsf{ATR}_0^{\mathrm{set}}$. As in §V.6, let CWO be the assertion of *comparability of countable well orderings*, i.e.,

$$\forall X\, \forall Y\, ((\mathrm{WO}(X) \wedge \mathrm{WO}(Y)) \rightarrow (|X| \leq |Y| \vee |X| \geq |Y|)).$$

By theorem V.6.8 it suffices to show that CWO is a theorem of $\mathsf{ATR}_0^{\mathrm{set}}$. We reason within $\mathsf{ATR}_0^{\mathrm{set}}$. Let $X, Y \subseteq \omega$ be (codes for) countable well orderings, i.e., assume $\mathrm{WO}(X)$ and $\mathrm{WO}(Y)$. Set $r_X = \{\langle n, m\rangle : n <_X m\}$. Then $r_X$ is a regular relation, so by Axiom Beta let $f_X$ be the collapsing function of $r_X$, i.e., $\mathrm{dom}(f_X) = \mathrm{field}(r_X)$ and $f'_X m = f''\{n: \langle n, m\rangle \in r_X\}$ for all $m \in \mathrm{field}(r_X)$. Put $\alpha_X = \mathrm{rng}(f_X)$. It is easy to check that $\alpha_X$ is an ordinal, the order type of $X$, and that $f_X$ is the unique isomorphism of $X$ with $\alpha_X$. Similarly define $r_Y$ and let $f_Y$ be the unique isomorphism of $Y$ with its order type $\alpha_Y$. By part 3 of VII.3.7, we have either $\alpha_X \leq \alpha_Y$ or $\alpha_Y \leq \alpha_X$. Suppose for definiteness that $\alpha_X \leq \alpha_Y$. Put

$$g = \{(m, n): m \in \mathrm{field}(X) \wedge n \in \mathrm{field}(Y) \wedge f'_X m = f'_Y n\}.$$

Then clearly $g: |X| \leq |Y|$. Similarly if $\alpha_Y \leq \alpha_X$ we have $g: |X| \geq |Y|$. This completes the proof. □

In the previous theorem we exhibited the natural translation of $\mathsf{ATR}_0$ into $\mathsf{ATR}_0^{\mathrm{set}}$. Our next goal is to obtain an adjoint translation from $\mathsf{ATR}_0^{\mathrm{set}}$ into $\mathsf{ATR}_0$.

DEFINITION VII.3.10 (suitable trees). In $\mathsf{ATR}_0$ we define a *suitable tree* to be a set $T \subseteq \mathbb{N}^{<\mathbb{N}}$ such that

(i) $T$ is a tree, i.e.,
$$\forall \tau\, \forall m\, ((\tau \in T \wedge m \leq \mathrm{lh}(\tau)) \rightarrow \tau[m] \in T);$$
(ii) $T$ is nonempty (equivalently $\langle\rangle \in T$ where $\langle\rangle$ is the empty element of $\mathbb{N}^{<\mathbb{N}}$); and
(iii) $T$ is well founded, i.e., has no path, i.e.,
$$\neg(\exists f : \mathbb{N} \rightarrow \mathbb{N})\, \forall m\, (f[m] \in T).$$

If $T$ is a suitable tree and $\sigma \in T$, we put
$$T^\sigma = \{\tau : \sigma^\frown\tau \in T\}.$$
Note that $T^\sigma$ is again a suitable tree.

DEFINITION VII.3.11. By theorem VII.3.9 the above definition of suitable tree in $\mathsf{ATR}_0$ carries over to $\mathsf{ATR}_0^{\mathrm{set}}$. Continuing in $\mathsf{ATR}_0^{\mathrm{set}}$, given a suitable tree $T$ we put
$$r_T = \{\langle \sigma^\frown\langle n\rangle, \sigma\rangle : \sigma^\frown\langle n\rangle \in T\}.$$
Then $r_T$ is a regular relation. By Axiom Beta let $c_T$ be the collapsing function of $r_T$. Define
$$|T| = c'_T\langle\rangle = c''_T\{\langle n\rangle : \langle n\rangle \in T\}.$$
Note that $|T^\sigma| = c'_T\sigma$ for all $\sigma \in T$.

The idea of our translation of $\mathsf{ATR}_0^{\mathrm{set}}$ into $\mathsf{ATR}_0$ will be that the suitable tree $T$ is a code for the hereditarily countable set $|T|$.

LEMMA VII.3.12. *Within* $\mathsf{ATR}_0^{\mathrm{set}}$ *we can prove that for any set* $u$ *there exists a suitable tree* $T$ *such that* $|T| = u$.

PROOF. We reason within $\mathsf{ATR}_0^{\mathrm{set}}$. Let $u$ be given. By the Axiom of Countability, there exists an injection $g$ such that $\mathrm{dom}(g) \subseteq \omega$, $\mathrm{rng}(g)$ is transitive, and $u \subseteq \mathrm{rng}(g)$. Let $T \subseteq \mathbb{N}^{<\mathbb{N}}$ consist of $\langle\rangle$ plus all $\langle m_0, \ldots, m_k\rangle$ such that $g'm_0 \in u$ and $\forall i\, (i < k \rightarrow g'm_{i+1} \in g'm_i)$. It is easy to check that $T$ is a suitable tree and $|T| = u$. □

DEFINITION VII.3.13 ($=^*$ and $\in^*$ for suitable trees). Within $\mathsf{ATR}_0^{\mathrm{set}}$, let $T$ be a suitable tree. We write $\mathrm{Iso}(X, T)$ to mean that $X \subseteq T \times T$ and, for all $(\sigma, \tau) \in T \times T$, $(\sigma, \tau) \in X$ if and only if
$$\forall m\, (\sigma^\frown\langle m\rangle \in T \rightarrow \exists n\, (\sigma^\frown\langle m\rangle, \tau^\frown\langle n\rangle) \in X)$$
and
$$\forall n\, (\tau^\frown\langle n\rangle \in T \rightarrow \exists m\, (\sigma^\frown\langle m\rangle, \tau^\frown\langle n\rangle) \in X).$$

If $S$ and $T$ are suitable trees, we define $S \oplus T$ to be the suitable tree consisting of $\langle\rangle$ plus all $\langle 0\rangle^\frown\sigma$ and $\langle 1\rangle^\frown\tau$ such that $\sigma \in S$ and $\tau \in T$. We define

$$S =^* T \leftrightarrow \exists X\,(\mathrm{Iso}(X, S \oplus T) \wedge (\langle 0\rangle, \langle 1\rangle) \in X))$$

and

$$S \in^* T \leftrightarrow \exists X\,(\mathrm{Iso}(X, S \oplus T) \wedge \exists n\,(\langle 0\rangle, \langle 1, n\rangle) \in X)).$$

LEMMA VII.3.14. *Within* $\mathsf{ATR}_0^{\mathrm{set}}$ *we can prove that, for all suitable trees* $S$ *and* $T$,

$$S =^* T \leftrightarrow |S| = |T|,$$

*and*

$$S \in^* T \leftrightarrow |S| \in |T|.$$

PROOF. Given a suitable tree $T$, put

$$X = \{(\sigma, \tau)\colon \sigma \in T \wedge \tau \in T \wedge c'_T\sigma = c'_T\tau\}.$$

Then clearly $X$ is the unique set such that $\mathrm{Iso}(X, T)$. Applying this to the suitable tree $S \oplus T$ instead of $T$, we obtain the desired conclusions. □

DEFINITION VII.3.15. Let $V_i$, $i \in \omega$ be fixed distinct set variables of $\mathrm{L}_2$. We shall use these variables to denote suitable trees. We shall link $V_i$ to the set-theoretic variable $v_i$ (cf. definition VII.3.1). To each formula $\varphi$ of $\mathrm{L}_{\mathrm{set}}$, we associate a formula $|\varphi|$ of $\mathrm{L}_2$ as follows.

$$|v_i = v_j| \text{ is } V_i =^* V_j;$$
$$|v_i \in v_j| \text{ is } V_i \in^* V_j;$$
$$|\neg\varphi| \text{ is } \neg|\varphi|; |\varphi \wedge \psi| \text{ is } |\varphi| \wedge |\psi|; \text{ etc.};$$
$$|\forall v_i\,\varphi| \text{ is } \forall V_i\,(V_i \text{ suitable} \rightarrow |\varphi|);$$
$$|\exists v_i\,\varphi| \text{ is } \exists V_i\,(V_i \text{ suitable} \wedge |\varphi|).$$

Note that if $v_{i_1}, \ldots, v_{i_k}$ are the free variables of $\varphi$, then $V_{i_1}, \ldots, V_{i_k}$ are the free variables of $|\varphi|$.

LEMMA VII.3.16. *Let* $\varphi$ *be any formula of* $\mathrm{L}_{\mathrm{set}}$. *Let* $v_{i_1}, \ldots, v_{i_k}$ *be the free variables of* $\varphi$. *Then* $\mathsf{ATR}_0^{\mathrm{set}}$ *proves the following. For all sets* $v_{i_1}, \ldots, v_{i_k}$ *and all suitable trees* $V_{i_1}, \ldots, V_{i_k}$ *such that* $|V_{i_1}| = v_{i_1}, \ldots, |V_{i_k}| = v_{i_k}$, *we have* $\varphi \leftrightarrow |\varphi|$. *In particular,* $\mathsf{ATR}_0^{\mathrm{set}}$ *proves* $\varphi \leftrightarrow |\varphi|$ *for all sentences* $\varphi$ *of* $\mathrm{L}_{\mathrm{set}}$.

PROOF. This follows by a straightforward induction on the number of symbols in $\varphi$, using lemmas VII.3.14 and VII.3.12. □

Our next task is to show that the set-theoretic properties of suitable trees can be proved in $\mathsf{ATR}_0$.

LEMMA VII.3.17. *The following is provable in* $\mathsf{ATR}_0$. *Let* $T$ *be a suitable tree. Then there exists a unique set* $X$ *such that* $\mathrm{Iso}(X, T)$. *Furthermore, for all* $\sigma \in T$ *and* $\tau \in T$, *we have*

$$T^\sigma =^* T^\tau \leftrightarrow (\sigma, \tau) \in X$$

*and*

$$T^\sigma \in^* T^\tau \leftrightarrow \exists n\, ((\sigma, \tau^\frown \langle n \rangle) \in X).$$

*In particular,* $X$ *is an equivalence relation on* $T$.

PROOF. The existence of $X$ is proved by arithmetical transfinite recursion along (the Kleene/Brouwer ordering of) $T$. The uniqueness is proved by arithmetical transfinite induction. The rest is straightforward using the fact that, for each $\rho \in T$, if we define

$$X^\rho = \{(\sigma, \tau) \colon (\rho^\frown \sigma, \rho^\frown \tau) \in X\}$$

then $\mathrm{Iso}(X^\rho, T^\rho)$ holds. □

DEFINITION VII.3.18. In $\mathsf{ATR}_0$, for $X \subseteq \mathbb{N}$ we define $X^*$ to be the suitable tree consisting of $\langle\rangle$ and all $\langle m_0, \dots, m_k \rangle$ such that $m_0 \in X$ and $\forall i\, (i < k \to m_{i+1} < m_i)$. For $n \in \mathbb{N}$ we define $n^* = X^*$ where $X = \{0, \dots, n-1\}$.

The point of the previous definition is that, provably in $\mathsf{ATR}_0^{\mathrm{set}}$, $|X^*| = X$ and $|n^*| = n$. Thus $n \in X$ if and only if $n^* \in^* X^*$. This is a special case of:

LEMMA VII.3.19. *Let* $\varphi$ *be any formula of* $\mathrm{L}_2$. *Let* $X_1, \dots, X_i, n_1, \dots, n_j$ *be the free variables of* $\varphi$. *Then* $\mathsf{ATR}_0$ *proves the following. For all suitable trees* $V_1, \dots, V_i, V_{i+1}, \dots, V_{i+j}$ *such that* $V_1 =^* X_1^*, \dots, V_i =^* X_i^*$, $V_{i+1} =^* n_1^*, \dots, V_{i+j} =^* n_j^*$, *we have* $\varphi \leftrightarrow |\varphi|$.

PROOF. The proof is by a straightforward induction on the number of symbols in $\varphi$. We omit the details. □

LEMMA VII.3.20. *Let* $\varphi$ *be any one of the axioms of* $\mathsf{ATR}_0^{\mathrm{set}}$. *Then* $|\varphi|$ *is a theorem of* $\mathsf{ATR}_0$.

PROOF. We reason within $\mathsf{ATR}_0$. The proofs of |Axiom of Equality| and |Axiom of Extensionality| are straightforward, using lemma VII.3.17.

In order to handle the Axiom of Rudimentary Closure, we construct appropriate suitable trees. For example, given suitable trees $V_0$ and $V_1$, we can construct a suitable tree

$$V_2 = V_0 \oplus V_1 = \{\langle\rangle\} \cup \{\langle 0 \rangle^\frown \tau \colon \tau \in V_0\} \cup \{\langle 1 \rangle^\frown \tau \colon \tau \in V_1\}.$$

It is then straightforward to prove that for all suitable trees $V_3$,

$$V_3 \in^* V_2 \leftrightarrow (V_3 =^* V_0 \vee V_3 =^* V_1)$$

i.e., $|\forall v_3\, (v_3 \in v_2 \leftrightarrow (v_3 = v_0 \vee v_3 = v_1)|$. This shows that

$$|\forall v_0\, \forall v_1\, \exists v_2 \forall v_3\, (v_3 \in v_2 \leftrightarrow (v_3 = v_0 \vee v_3 = v_1))|,$$

i.e., $|\forall v_0\, \forall v_1\, \exists\, \{v_0, v_1\}|$. The other parts of |Rudimentary Closure| are proved similarly.

In order to dispose of the Axiom of Infinity, we construct a suitable tree $V_0$ in accordance with the usual coding of the hereditarily finite sets. Put $n\mathrm{E}m$ if and only if $n$ occurs as an exponent in the binary expansion of $m$, i.e., if $n = m_i$ for some $i$ where

$$m = 2^{m_1} + 2^{m_2} + \cdots + 2^{m_j}, \qquad m_1 > m_2 > \cdots > m_j.$$

We then let $V_0$ be the suitable tree consisting of $\langle\rangle$ plus all $\langle n_0, \ldots, n_k\rangle$ such that $n_{i+1}\mathrm{E}n_i$ for all $i < k$. With this $V_0$ it is straightforward to prove

$$|\emptyset \in v_0 \wedge \forall v_1\, \forall v_2\, ((v_1 \in v_0 \wedge v_2 \in v_0) \rightarrow v_1 \cup \{v_2\} \in v_0)|,$$

hence |Axiom of Infinity|. We could also prove $|v_0 = \mathrm{HF}|$, but this is not needed.

We now prove |Axiom of Regularity|. Let $V_0$ be a suitable tree such that $|v_0 \neq \emptyset|$, i.e., $\exists m\, (\langle m\rangle \in V_0)$. By lemma VII.3.17 let $X_0$ be such that $\mathrm{Iso}(X_0, V_0)$. Suppose for a contradiction that

$$|\forall v_1\, (v_1 \in v_0 \rightarrow \exists v_2\, (v_2 \in v_0 \wedge v_2 \in v_1))|.$$

By lemma VII.3.17 this is equivalent to

$$\forall m\, (\langle m\rangle \in V_0 \rightarrow \exists n\, \exists j\, ((\langle n\rangle, \langle m, j\rangle) \in X_0)).$$

Define $f : \mathbb{N} \rightarrow \mathbb{N}$ by recursion as follows. Put $f(0) =$ the least $m$ such that $\langle m\rangle \in V_0$. Given $f[k+1] = \langle f(0), \ldots, f(k)\rangle$, put $f(k+1) =$ the least $j$ such that $\exists n\, ((\langle n\rangle, f[k]^\frown\langle j\rangle) \in X_0)$. Then $\forall k\, (f[k] \in V_0)$ contradicting the well foundedness of $V_0$.

The remaining two axioms involve ordered pairs. Note that $|\langle v_i, v_j\rangle = v_k|$ is equivalent to

$$(V_i \oplus V_j) \oplus (V_j \oplus V_j) =^* V_k.$$

To prove |Axiom Beta|, let $V_0$ be a given suitable tree such that

$$|v_0 \text{ is a regular relation}|.$$

Let $X$ be the set of all $\langle k, i, m\rangle$ such that $\langle k, i, m\rangle \in V_0$. Let $V_1$ consist of $\langle\rangle$ plus all $\langle\sigma\rangle^\frown\tau$ such that $\sigma \in X$ and $\tau \in V_0^\sigma$. It is easy to check that $V_1$ is a suitable tree, and that

$$\left|v_1 = \bigcup\bigcup\bigcup v_0 = \mathrm{field}(v_0)\right|.$$

Now by lemma VII.3.17 let $X_0$ be such that $\mathrm{Iso}(X_0, V_0)$. Let $R$ be the set of all $(\sigma, \tau) \in X \times X$ such that for some $i, j, k, m, n, p$ and $p$ we have $(\tau, \langle k, i, n\rangle) \in X_0$, $(\sigma, \tau) \notin X_0$, $(\langle k, i\rangle, \langle k, j\rangle) \notin X_0$, $(\sigma, \langle k, j, p\rangle) \in X_0$. Let $V_2$ consist of $\langle\rangle$ plus all $\langle\sigma_0, \ldots, \sigma_k\rangle$ such that $\forall i\, (i < k \rightarrow (\sigma_i, \sigma_{i+1}) \in R)$. Let $V_3$ consist of $\langle\rangle$ plus all $\langle\sigma\rangle^\frown\tau$ such that $\sigma \in X$ and

$$\tau \in (V_2^{\langle\sigma\rangle} \oplus V_0^\sigma) \oplus (V_0^\sigma \oplus V_0^\sigma).$$

It is straightforward to check that $V_2$ and $V_3$ are suitable trees, and that

$$|v_2 = \mathrm{rng}(v_3) \text{ where } v_3 \text{ is the collapsing function of } v_0|.$$

It remains to prove |Axiom of Countability|. Let $V_0$ be a given suitable tree. We may regard each $\sigma \in V_0 \subseteq \mathbb{N}$ as an element of $\mathbb{N}$ and form the corresponding suitable tree $\sigma^*$ as in definition VII.3.18. Let $V_1$ consist of $\langle\rangle$ plus all $\langle\sigma\rangle^\frown\tau$ such that $\sigma \in V_0$ and $\tau \in (V_0^\sigma \oplus \sigma^*) \oplus (\sigma^* \oplus \sigma^*)$. It is straightforward to check that $|\mathrm{Fcn}(v_1) \wedge \mathrm{dom}(v_1) \subseteq \omega \wedge \mathrm{Trans}(\mathrm{rng}(v_1)) \wedge v_0 \subseteq \mathrm{rng}(v_1)|$.

This completes the proof of lemma VII.3.20. □

EXERCISE VII.3.21. Show that $\mathsf{ATR}_0^{\mathrm{set}}$ proves, for all sets $v$, the proper existence of

$$\mathrm{TC}(v) = \bigcup \left\{ \bigcup^n v : n \in \omega \right\}$$

where $\bigcup^0 v = v$ and $\bigcup^{n+1} v = \bigcup \bigcup^n v$ for all $n \in \omega$. Also, $\mathsf{ATR}_0^{\mathrm{set}}$ proves that $\mathrm{TC}(v)$ is the smallest transitive set $u$ such that $v \subseteq u$. $\mathrm{TC}(v)$ is known as the *transitive closure of* $v$.

We are now ready to deduce the main results of this section.

THEOREM VII.3.22. *Let $\varphi$ be a sentence of $\mathrm{L}_{\mathrm{set}}$. Then $\mathsf{ATR}_0^{\mathrm{set}}$ proves $\varphi$ if and only if $\mathsf{ATR}_0$ proves $|\varphi|$.*

PROOF. Suppose first that $\mathsf{ATR}_0^{\mathrm{set}}$ proves $\varphi$. By lemma VII.3.20 it follows that $\mathsf{ATR}_0$ proves $|\varphi|$. Conversely, suppose that $\mathsf{ATR}_0$ proves $|\varphi|$. It follows by theorem VII.3.9 that $\mathsf{ATR}_0^{\mathrm{set}}$ proves $|\varphi|$. But then by lemma VII.3.16 it follows that $\mathsf{ATR}_0^{\mathrm{set}}$ proves $\varphi$. □

THEOREM VII.3.23 (a conservation theorem). *$\mathsf{ATR}_0^{\mathrm{set}}$ is a conservative extension of $\mathsf{ATR}_0$. In other words, for any sentence $\varphi$ of $\mathrm{L}_2$, $\mathsf{ATR}_0^{\mathrm{set}}$ proves $\varphi$ if and only if $\mathsf{ATR}_0$ proves $\varphi$.*

PROOF. By theorem VII.3.22, $\mathsf{ATR}_0^{\mathrm{set}}$ proves $\varphi$ if and only if $\mathsf{ATR}_0$ proves $|\varphi|$. But by lemma VII.3.19 $\mathsf{ATR}_0$ proves $|\varphi| \leftrightarrow \varphi$, so the desired conclusion follows. □

For use in §§VII.4 and VII.5, we prove the following theorem which relates the set-theoretic hierarchy $\Sigma^{\mathrm{set}}_k$, $k < \omega$ (definition VII.3.4) to the projective hierarchy $\Sigma^1_{k+1}$, $k < \omega$ (definition I.5.1).

THEOREM VII.3.24. *Assume $0 \leq k < \omega$.*

1. *If $\varphi$ is a $\Sigma^{\mathrm{set}}_k$ formula of $\mathrm{L}_{\mathrm{set}}$, then $|\varphi|$ is equivalent (provably in $\mathsf{ATR}_0^{\mathrm{set}}$) to a $\Sigma^1_{k+1}$ formula of $\mathrm{L}_2$.*
2. *Conversely, each $\Sigma^1_{k+2}$ formula of $\mathrm{L}_2$ is equivalent (provably in $\mathsf{ATR}_0^{\mathrm{set}}$) to a $\Sigma^{\mathrm{set}}_{k+1}$ formula of $\mathrm{L}_{\mathrm{set}}$.*

PROOF. We first show by induction on $\Delta^{\mathrm{set}}_0$ formulas $\varphi$ that $|\varphi|$ is equivalent to a $\Sigma^1_1$ formula. By definitions VII.3.15 and VII.3.13, $|v_i = v_j|$ and

$|v_i \in v_j|$ are equivalent to the $\Sigma^1_1$ formulas

$$\exists X\,(\mathrm{Iso}(X, V_i \oplus V_j) \wedge (\langle 0\rangle, \langle 1\rangle) \in X)$$

and

$$\exists X\,(\mathrm{Iso}(X, V_i \oplus V_j) \wedge \exists n\,((\langle 0\rangle, \langle 1, n\rangle) \in X))$$

respectively. Hence, by lemmas VII.3.9 and VII.3.17, $|v_i \neq v_j|$ and $|v_i \notin v_j|$ are equivalent to the $\Sigma^1_1$ formulas

$$\exists X\,(\mathrm{Iso}(X, V_i \oplus V_j) \wedge (\langle 0\rangle, \langle 1\rangle) \notin X)$$

and

$$\exists X\,(\mathrm{Iso}(X, V_i \oplus V_j) \wedge \forall n\,(\langle 0\rangle, \langle 1, n\rangle) \notin X)$$

respectively. It is also clear that if $|\varphi|$ and $|\psi|$ are $\Sigma^1_1$, then so are $|\varphi| \wedge |\psi|$ and $|\varphi| \vee |\psi|$, i.e., $|\varphi \wedge \psi|$ and $|\varphi \vee \psi|$. Finally, by lemma VII.3.17, $|\forall v_i\,(v_i \in v_j \to \varphi)|$ and $|\exists v_i\,(v_i \in v_j \wedge \varphi)|$ are equivalent to

$$\forall n\,(\langle n\rangle \in V_j \to \exists V_i\,(V_i =^* V_j^{\langle n\rangle} \wedge |\varphi|))$$

and

$$\exists n\,(\langle n\rangle \in V_j \wedge \exists V_i\,(V_i =^* V_j^{\langle n\rangle} \wedge |\varphi|))$$

respectively. These formulas are $\Sigma^1_1$ if $|\varphi|$ is. At this point we are using the $\Sigma^1_1$ axiom of choice, a consequence of $\mathsf{ATR}_0$ (theorem V.8.3).

So far we have shown that $\varphi$ $\Sigma^{\mathrm{set}}_0$ implies $|\varphi|$ $\Sigma^1_1$. Suppose now that $\varphi$ is $\Sigma^{\mathrm{set}}_{k+1}$, say $\exists v_i\,\psi$ where $\psi$ is $\Pi^{\mathrm{set}}_k$. By induction on $k$, $|\psi|$ is $\Pi^1_{k+1}$. Hence $|\varphi|$, i.e.,

$$\exists V_i\,(V_i \text{ suitable} \wedge |\psi|),$$

is $\Sigma^1_{k+2}$. This completes the proof of part 1.

We now prove the converse. Let $\varphi$ be a $\Sigma^1_2$ formula of $\mathrm{L}_2$. By lemma V.1.4 (the Kleene normal form theorem), we can write $\varphi$ in the form

$$\exists X\,\forall f\,\exists n\,\neg\theta(X, f[n])$$

where $\theta$ is arithmetical. We may also assume that $\theta(X, f[n])$ implies $\theta(X, f[m])$ for all $m \leq n$. Thus $\forall f\,\exists n\,\neg\theta(X, f[n])$ is equivalent to regularity of the relation $\{\langle \tau^\frown\langle k\rangle, \tau\rangle : \theta(X, \tau^\frown\langle k\rangle)\}$. By Axiom Beta and the Axiom of Regularity, this is equivalent to the existence of an appropriate collapsing function. Thus $\varphi$ is equivalent to the $\Sigma^{\mathrm{set}}_1$ formula

$$\exists X\,\exists g\,(\mathrm{Fcn}(g) \wedge \forall \tau\,\forall k\,(\theta(X, \tau^\frown\langle k\rangle) \to g'\tau^\frown\langle k\rangle \in g'\tau)).$$

The previous paragraph shows that every $\Sigma^1_2$ formula of $\mathrm{L}_2$ is equivalent to a $\Sigma^{\mathrm{set}}_1$ formula of $\mathrm{L}_{\mathrm{set}}$. It follows easily that every $\Sigma^1_{k+2}$ formula of $\mathrm{L}_2$ is equivalent to a $\Sigma^{\mathrm{set}}_{k+1}$ formula of $\mathrm{L}_{\mathrm{set}}$.

This completes the proof of theorem VII.3.24. □

Theorems VII.3.22 and VII.3.23 established a close and precise relationship of mutual interpretability between $\mathsf{ATR}_0$ (a subsystem of second order arithmetic) and $\mathsf{ATR}_0^{\mathrm{set}}$ (a system of set theory). We shall now reformulate these results in model-theoretic terms.

Definition VII.3.25.

1. A *model for* $\mathrm{L}_{\mathrm{set}}$ or $\mathrm{L}_{\mathrm{set}}$*-structure* is an ordered pair
$$A = (|A|, \in_A)$$
where $|A|$ is a nonempty set and $\in_A \subseteq |A| \times |A|$ is a binary relation on $|A|$.
2. Let $\varphi$ be a sentence of $\mathrm{L}_{\mathrm{set}}$ with parameters from $|A|$. We say that $A$ *satisfies* $\varphi$ or *is a model of* $\varphi$, written $A \models \varphi$, if $\varphi$ is true when the variables are interpreted as ranging over $|A|$, $\in$ is interpreted as $\in_A$, $=$ is interpreted as
$$=_A \; = \{\langle a, a\rangle : a \in |A|\},$$
and the parameters are interpreted as themselves.
3. The model $A$ is said to be *well founded* if there is no infinite sequence $\langle a_n : n < \omega\rangle$ such that $a_{n+1} \in_A a_n$ for all $n < \omega$.
4. The model $A$ is said to be *transitive* if $|A|$ is a transitive set and
$$\in_A \; = \in \restriction |A|.$$

It can be shown (in ZF, for instance) that any transitive $\mathrm{L}_{\mathrm{set}}$-structure satisfies the Axiom of Extensionality and is well founded. Conversely, any well founded $\mathrm{L}_{\mathrm{set}}$-structure which satisfies the Axiom of Extensionality is uniquely isomorphic to a transitive model.

Definition VII.3.26. To any model $A = (|A|, \in_A)$ of $\mathsf{B}_0^{\mathrm{set}}$ we canonically associate a model
$$A^2 = M = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$
of $\mathsf{ACA}_0$. Namely $|M| = \{a \in |A| : A \models \mathrm{FinOrd}(a)\}$; $\mathcal{S}_M = \{b_A : A \models b \subseteq \omega\}$ where $b_A = \{a \in |A| : A \models a \in b\}$; and $+_M$, $\cdot_M$, $0_M$, $1_M$, $<_M$ are defined in the natural way (cf. the proof of theorem VII.3.9).

Theorem VII.3.27. *Let $A$ be a model of $\mathsf{ATR}_0^{\mathrm{set}}$. Then*:

1. *$A^2$ is a model of $\mathsf{ATR}_0$;*
2. *$A^2$ is a $\beta$-model if and only if $A$ is well founded.*

Proof. Part 1 is an immediate consequence of theorem VII.3.9. Part 2 follows easily. □

In the opposite direction, we have:

Definition VII.3.28. To any model
$$M = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$

for $L_2$ we associate a model $M_{\text{set}}$ for $L_{\text{set}}$ as follows. Put

$$\mathcal{T}_M = \{T \in \mathcal{S}_M : M \models T \text{ is a suitable tree}\}$$

For $T \in \mathcal{T}_M$ put

$$[T] = \{T' \in \mathcal{T}_M : M \models T =^* T'\}$$

and define

$$|A| = \{[T]: T \in \mathcal{T}_M\}.$$

For $T, T' \in \mathcal{T}_M$ define $[T] \in_A [T']$ if and only if $M \models T \in^* T'$. Thus $A = (|A|, \in_A)$ is a model for $L_{\text{set}}$, and we define

$$M_{\text{set}} = A = (|A|, \in_A).$$

It can be shown that if $M$ is model of $\mathsf{ACA}_0$, then $M_{\text{set}}$ is a model of $\mathsf{B}_0^{\text{set}}$.

THEOREM VII.3.29. *Let $M$ be a model of $\mathsf{ATR}_0$. Then $M_{\text{set}}$ is a model of $\mathsf{ATR}_0^{\text{set}}$. Furthermore $(M_{\text{set}})^2 = M$ up to a canonical isomorphism. Conversely, if $A$ is a model of $\mathsf{ATR}_0^{\text{set}}$, then $(A^2)_{\text{set}} = A$ up to a canonical isomorphism.*

PROOF. This is an immediate consequence of lemmas VII.3.20, VII.3.19, VII.3.12 and VII.3.14. □

DEFINITION VII.3.30. Let $A = (|A|, \in_A)$ and $B = (|B|, \in_B)$ be models for $L_{\text{set}}$. We say that $A$ is a *transitive submodel of* $B$, written $A \subseteq_{\text{trans}} B$, if $|A| \subseteq |B|$ and, for all $a \in |A|$ and $b \in |B|$, $b \in_B a$ if and only if $b \in |A|$ and $b \in_A a$.

The above notion of transitive submodel ($\subseteq_{\text{trans}}$) is similar to the notion of $\beta$-submodel ($\subseteq_\beta$, definition VII.1.11). Thus $A$ is transitive if and only if $A \subseteq_{\text{trans}}$ the universe of ZF set theory. But in general, the models $A$ and $B$ in the above definition need not be transitive or even well founded.

THEOREM VII.3.31. *If $M'$ is a model of $\mathsf{ATR}_0$ and $M \subseteq_\beta M'$, then $M_{\text{set}}$ is (canonically isomorphic to) a transitive submodel of $M'_{\text{set}}$. Conversely, if $A$ and $B$ are models of $\mathsf{ATR}_0^{\text{set}}$ and $A \subseteq_{\text{trans}} B$, then $A^2$ is a $\beta$-submodel of $B^2$.*

PROOF. The formula "$T$ is a suitable tree" is $\Pi^1_1$. Hence $\mathcal{T}_M = \mathcal{S}_M \cap \mathcal{T}_{M'}$ and the first part of the theorem follows easily. The second part follows using Axiom Beta in $A$ and the Axiom of Regularity in $B$. □

Combining this with theorem VII.1.19, we obtain:

THEOREM VII.3.32. *Let $B$ be any countable model of $\mathsf{ATR}_0^{\text{set}}$. Then there exists a proper transitive submodel $A \subseteq_{\text{trans}} B$, $A \neq B$, such that $A$ is again a model of $\mathsf{ATR}_0^{\text{set}}$.*

PROOF. Theorems VII.3.27, VII.3.29 and VII.3.31 establish a canonical one-to-one correspondence between models of $\mathsf{ATR}_0^{\text{set}}$ and models of $\mathsf{ATR}_0$. Applying this to theorem VII.1.19, we obtain the desired result. □

We shall now end this section by generalizing its main result so as to apply to systems of second order arithmetic which are stronger than $\mathsf{ATR}_0$.

Definition VII.3.33. Let $T_0$ be any theory in the language $\mathrm{L}_2$ such that $\mathsf{ATR}_0 \subseteq T_0$, i.e., each axiom of $\mathsf{ATR}_0$ is a theorem of $T_0$. Define

$$T_0^{\mathrm{set}} = \mathsf{ATR}_0^{\mathrm{set}} + T_0,$$

i.e., $T_0^{\mathrm{set}}$ is that theory in the language $\mathrm{L}_{\mathrm{set}}$ whose axioms are those of $\mathsf{ATR}_0^{\mathrm{set}}$ plus (the natural translations into $\mathrm{L}_{\mathrm{set}}$, as in theorem VII.3.9, of) those of $T_0$.

Theorem VII.3.34. *Let $T_0$ be any $\mathrm{L}_2$-theory which includes $\mathsf{ATR}_0$. Then lemmas* VII.3.12, VII.3.14, VII.3.16, VII.3.17, VII.3.19, VII.3.20 *and theorems* VII.3.9, VII.3.22, VII.3.23, VII.3.24, VII.3.27, VII.3.29, VII.3.31 *continue to hold when $\mathsf{ATR}_0$ and $\mathsf{ATR}_0^{\mathrm{set}}$ are replaced by $T_0$ and $T_0^{\mathrm{set}}$ respectively. In particular, $T_0^{\mathrm{set}}$ is a conservative extension of $T_0$. Also, for all sentences $\varphi$ of $L_{\mathrm{set}}$, $T_0^{\mathrm{set}}$ proves $\varphi$ if and only if $T_0$ proves $|\varphi|$.*

For example, if $M$ is any $\mathrm{L}_2$-model, we have $M \models \Pi^1_1\text{-}\mathsf{CA}_0$ if and only if $M_{\mathrm{set}} \models \Pi^1_1\text{-}\mathsf{CA}_0^{\mathrm{set}}$. Note also that $M$ is a $\beta$-model if and only if $M_{\mathrm{set}}$ is well founded. (Compare this with our earlier characterization of $\beta$-models of $\Pi^1_1\text{-}\mathsf{CA}_0$, theorem VII.1.8.)

Proof. The results for $T_0 \supseteq \mathsf{ATR}_0$ are all immediate corollaries of the special case $T_0 = \mathsf{ATR}_0$. □

Remark VII.3.35. Theorem VII.3.32 does not in general hold with $\mathsf{ATR}_0^{\mathrm{set}}$ replaced by $T_0^{\mathrm{set}}$. For example, let $M$ be the unique minimum $\beta$-model of $\Pi^1_1\text{-}\mathsf{CA}_0$ (corollary VII.1.8). Then by theorem VII.3.34, $M_{\mathrm{set}}$ is the unique smallest (up to canonical isomorphism) well founded model of $\Pi^1_1\text{-}\mathsf{CA}_0^{\mathrm{set}}$. In particular, there is no proper transitive submodel of $M_{\mathrm{set}}$ which is again a model of $\Pi^1_1\text{-}\mathsf{CA}_0^{\mathrm{set}}$.

Exercise VII.3.36. Show that $\Pi^1_1\text{-}\mathsf{CA}_0^{\mathrm{set}}$ is equivalent to $\mathsf{ATR}_0^{\mathrm{set}}$ plus the axiom

$$\forall v\, \exists u\, (v \in u \wedge \mathrm{Trans}(u) \wedge \langle u, \in | u\rangle \models \mathsf{ATR}_0^{\mathrm{set}}).$$

Hint: Use theorem VII.2.10.

Exercise VII.3.37. Give a characterization of $\Pi^1_1\text{-}\mathsf{TR}_0^{\mathrm{set}}$ analogous to the above characterization of $\Pi^1_1\text{-}\mathsf{CA}_0^{\mathrm{set}}$. (See exercises VII.1.17 and VII.1.18.)

Exercise VII.3.38. Recall that $\Pi^1_\infty\text{-}\mathsf{TI}_0$ is the $\mathrm{L}_2$ theory consisting of $\mathsf{ACA}_0$ plus the transfinite induction scheme (see §VII.2). Show that $\Pi^1_\infty\text{-}\mathsf{TI}_0^{\mathrm{set}}$ is equivalent to $\mathsf{ATR}_0^{\mathrm{set}}$ plus the *$\in$-induction scheme*

$$\forall x\, (\forall y\, (y \in x \to \varphi(y)) \to \varphi(x)) \to \forall x\, \varphi(x),$$

where $\varphi(x)$ is an arbitrary formula of $\mathrm{L}_{\mathrm{set}}$.

EXERCISE VII.3.39. Show that $\Sigma^1_2$-$\mathsf{AC}_0^{\mathrm{set}}$ is equivalent to $\mathsf{ATR}_0^{\mathrm{set}}$ plus the scheme of $\Sigma_1^{\mathrm{set}}$ *collection*, i.e.,

$$\forall x\, \exists y\, \varphi(x, y) \to \forall u\, \exists v\, \forall x\, (x \in u \to \exists y\, (y \in v \wedge \varphi(x, y)))$$

where $\varphi(x, y)$ is any $\Sigma_1^{\mathrm{set}}$ formula and $v$ is a variable which does not occur freely in $\varphi(x, y)$.

EXERCISE VII.3.40. Characterize $T_0^{\mathrm{set}}$ when $T_0$ is any of the following $\mathrm{L}_2$-theories: $\Pi^1_{k+1}$-$\mathsf{CA}_0$, $\Delta^1_{k+2}$-$\mathsf{CA}_0$, $\Pi^1_k$-$\mathsf{TR}_0$, $\Sigma^1_{k+2}$-$\mathsf{AC}_0$, $\Sigma^1_{k+2}$-$\mathsf{DC}_0$, $\Pi^1_\infty$-$\mathsf{CA}_0$, $\Sigma^1_\infty$-$\mathsf{AC}_0$, $\Sigma^1_\infty$-$\mathsf{DC}_0$. (See also §§VII.5, VII.6 and VII.7.)

**Notes for §VII.3.** The ideas of this section can be traced to the work of Gödel [97, note 1] and Addison [4] relating the projective hierarchy to constructible sets. The fact that Axiom Beta is provable in ZF is due to Mostowski [192]. (Note: We use ZF to denote Zermelo/Fraenkel set theory including the Axiom of Regularity but not the axiom of choice.) In this context Axiom Beta is known as the Mostowski collapsing lemma. Also due to Mostowski [193] is the canonical one-to-one correspondence between $\beta$-models of $\Sigma^1_\infty$-$\mathsf{AC}_0$ and well founded models of $\mathsf{B}_0^{\mathrm{set}}$ plus the Axiom of Regularity plus the Axiom of Countability plus $\Sigma_\infty^{\mathrm{set}}$ collection. Barwise/Fisher [14] (see also Barwise [13, §V.8]) used Axiom Beta in their analysis of Shoenfield's absoluteness theorem (see also theorem VII.4.12 below). See also Abramson/Sacks [3]. The system $\mathsf{ATR}_0^{\mathrm{set}}$ and the idea of considering Axiom Beta as an alternative to $\Sigma_1^{\mathrm{set}}$ collection are due to Simpson [234] and independently to McAloon/Ressayre [183]. The one-to-one correspondence between models of $\mathsf{ATR}_0$ and models of $\mathsf{ATR}_0^{\mathrm{set}}$ is due to Simpson [234]. Theorems VII.1.19 and VII.3.32 are due to Simpson [234] in answer to a question of McAloon/Ressayre [183].

## VII.4. Constructible Sets and Absoluteness

We begin this section by developing some of the basic properties of Gödel's hierarchy of constructible sets within $\mathsf{ATR}_0^{\mathrm{set}}$. We then show that some of the more advanced properties, such as the Shoenfield absoluteness theorem, can be proved within $\Pi^1_1$-$\mathsf{CA}_0^{\mathrm{set}}$.

The reader of this section is assumed to be familiar with the definitions and results of §VII.3 above. In addition, some previous knowledge of constructible sets would be helpful although perhaps not absolutely indispensable.

LEMMA VII.4.1. *The following is provable in* $\mathsf{ATR}_0^{\mathrm{set}}$. *Let $u$ be a nonempty transitive set. There exists a unique set* $\mathrm{def}(u)$ *consisting of all $v \subseteq u$ such that $v$ is definable over the model $\langle u, \in \restriction u\rangle$ by a formula of* $\mathrm{L}_{\mathrm{set}}$ *with parameters from $u$.*

Proof. We reason within $\mathsf{ATR}_0^{\mathrm{set}}$. Let $u$ be a given nonempty transitive set. By the Axiom of Countability, let $g$ be an injection such that $\mathrm{dom}(g) = u$ and $\mathrm{rng}(g) \subseteq \omega$.

We shall employ a language $\mathrm{L}^u_{\mathrm{set}}$ which consists of $\mathrm{L}_{\mathrm{set}}$ augmented by constant symbols denoting the elements of $u$. We shall identify terms and formulas with their Gödel numbers. For each $i < \omega$, we have a variable $(0, i)$ denoted $v_i$ and intended to range over $u$. For each $a \in u$ we have a constant symbol $(1, g'a)$ denoted $\underline{a}$ and intended to denote $a$. The terms of $\mathrm{L}^u_{\mathrm{set}}$ are the variables $v_i$, $i < \omega$ and the constant symbols $\underline{a}$, $a \in u$. For all terms $s$ and $t$ we have formulas $(2, (s, t))$ and $(3, (s, t))$ denoted $s = t$ and $s \in t$ respectively. For all formulas $\varphi$ and $\psi$ we have formulas $(4, \varphi)$ and $(5, (\varphi, \psi))$ denoted $\neg\varphi$ and $\varphi \wedge \psi$ respectively. For all formulas $\varphi$ and variables $v_i$ we have a formula $(6, (v_i, \varphi))$ denoted $\forall v_i\, \varphi$. A sentence of $\mathrm{L}^u_{\mathrm{set}}$ is a formula of $\mathrm{L}^u_{\mathrm{set}}$ with no free variables. Let $\mathrm{S}^u$ be the set of sentences of $\mathrm{L}^u_{\mathrm{set}}$, and let $\mathrm{F}^u$ be the set of formulas of $\mathrm{L}^u_{\mathrm{set}}$ with at most one free variable. If $\varphi(v_i) \in \mathrm{F}^u$ with free variable $v_i$, then for each $a \in u$, $\varphi(\underline{a})$ is the sentence obtained by substituting the constant symbol $\underline{a}$ for each free occurrence of $v_i$.

By arithmetical transfinite recursion (theorem VII.3.9), there exists a valuation $f : \mathrm{S}^u \to \{0, 1\}$ satisfying the following inductive clauses:

$$f(\underline{a} = \underline{b}) = \begin{cases} 1 & \text{if } a = b, \\ 0 & \text{if } a \neq b; \end{cases}$$

$$f(\underline{a} \in \underline{b}) = \begin{cases} 1 & \text{if } a \in b, \\ 0 & \text{if } a \notin b; \end{cases}$$

$$f(\neg\varphi) = 1 - f(\varphi);$$

$$f(\varphi \wedge \psi) = \begin{cases} 1 & \text{if } f(\varphi) = f(\psi) = 1, \\ 0 & \text{otherwise;} \end{cases}$$

$$f(\forall v_i\, \varphi(v_i)) = \begin{cases} 1 & \text{if } f(\varphi(\underline{a})) = 1 \text{ for all } a \in u, \\ 0 & \text{otherwise.} \end{cases}$$

By arithmetical transfinite induction, $f$ is unique. Let $\mathrm{T}^u$ be the suitable tree consisting of $\langle\rangle$ plus all $\langle\varphi(v_i)\rangle$ such that $\varphi(v_i) \in \mathrm{F}^u$, plus all $\langle\varphi(v_i), \underline{a_0}, \ldots, \underline{a_k}\rangle$ such that $\varphi(v_i) \in \mathrm{F}^u$, $f(\varphi(\underline{a_0})) = 1$, and $f(\underline{a_{i+1}} \in \underline{a_i}) = 1$ for all $i < k$. Then clearly $|\mathrm{T}^u| = \mathrm{def}(u)$. This proves the existence of $\mathrm{def}(u)$. The uniqueness is straightforward. (Note that, although we used $g$ to prove the existence of $\mathrm{def}(u)$, the set $\mathrm{def}(u)$ does not depend on the choice of $g$.) □

Lemma VII.4.2 (the constructible hierarchy). *The following is provable in* $\mathsf{ATR}_0^{\mathrm{set}}$. *Let $u$ be a nonempty transitive set. Let $\gamma$ be an ordinal. There*

*exists a unique set* $\mathrm{L}^u_\gamma$ *such that*

$$\exists f\,(\mathrm{Fcn}(f) \wedge \mathrm{dom}(f) = \gamma + 1 \wedge f'\gamma = \mathrm{L}^u_\gamma \\ \wedge f'0 = u \wedge \forall\alpha\,(\alpha < \gamma \to f'\alpha + 1 = \mathrm{def}(f'\alpha)) \\ \wedge \forall\delta\,((\delta \leq \gamma \wedge \mathrm{Lim}(\delta)) \to f'\delta = \bigcup f''\delta)).$$

PROOF. We reason within $\mathsf{ATR}^{\mathrm{set}}_0$. Let $u$ be a nonempty transitive set and let $\gamma$ be an ordinal. By the Axiom of Countability, let $g$ be an injection such that $\mathrm{dom}(g) = \gamma \cup u$ and $\mathrm{rng}(g) \subseteq \omega$.

We shall employ a ramified language. For each $i < \omega$ and $\alpha < \gamma$, we have a variable $(0, (i, g'\alpha))$ denoted $v^\alpha_i$ and intended to range over $\mathrm{L}^u_\alpha$. For each $a \in u$ we have a constant symbol $(1, g'a)$ denoted $\underline{a}$ and intended to denote $a$. Each variable $v^\alpha_i$, $i < \omega$, $\alpha < \gamma$ is a term of rank $\alpha$. Each constant symbol $\underline{a}$, $a \in u$, is a closed term of rank 0. There are other closed terms, to be described below. For all terms $s$ and $t$, we have formulas $(2, (s, t))$ and $(3, (s, t))$ denoted $s = t$ and $s \in t$ respectively. For all formulas $\varphi$ and $\psi$, we have formulas $(4, \varphi)$ and $(5, (\varphi, \psi))$ denoted $\neg\varphi$ and $\varphi \wedge \psi$ respectively. For all formulas $\varphi$ and variables $v^\alpha_i$ we have a formula $(6, (v^\alpha_i, \varphi))$ denoted $\forall v^\alpha_i\,\varphi$. The rank of a formula is defined to be the maximum of the ranks of the terms occurring in it. If $\varphi(v^\alpha_i)$ is a formula of rank $\alpha$ with unique free variable $v^\alpha_i$, we have a closed term $(7, (v^\alpha_i, \varphi))$ denoted $\{v^\alpha_i : \varphi(v^\alpha_i)\}$ and intended to denote

$$\{x : x \in \mathrm{L}^u_\alpha \wedge \langle \mathrm{L}^u_\alpha, \in\restriction \mathrm{L}^u_\alpha\rangle \models \varphi(x)\};$$

this will be a typical element of $\mathrm{def}(\mathrm{L}^u_\alpha) = \mathrm{L}^u_{\alpha+1}$. The rank of the closed term $\{v^\alpha_i : \varphi(v^\alpha_i)\}$ is $\alpha + 1$.

Let $\mathrm{S}^u_\gamma$ be the set of all sentences of rank $< \gamma$. Let $\mathrm{F}^u_\gamma$ be the set of all formulas $\varphi(v^\alpha_i)$ of rank $\alpha$ with at most one free variable $v^\alpha_i$, $i < \omega$, $\alpha < \gamma$.

By arithmetical transfinite recursion (theorem VII.3.9), there exists a valuation $f : \mathrm{S}^u_\gamma \to \{0, 1\}$ satisfying:

$$f(\neg\varphi) = 1 - f(\varphi);$$

$$f(\varphi \wedge \psi) = \begin{cases} 1 & \text{if } f(\varphi) = f(\psi) = 1, \\ 0 & \text{otherwise;} \end{cases}$$

$$f(\forall v^\alpha_i\,\varphi(v^\alpha_i)) = \begin{cases} 1 & \text{if } f(\varphi(s)) = 1 \text{ for all closed terms } s \text{ of rank } \leq \alpha, \\ 0 & \text{otherwise.} \end{cases}$$

and, for all closed terms $s$ and $t$, the following inductive clauses for $f(s = t)$ and $f(s \in t)$.

Case 1: $\operatorname{rank}(s) = \alpha + 1$ and $\operatorname{rank}(t) = \beta + 1$. Say $s = \{v_i^\alpha : \varphi(v_i^\alpha)\}$ and $t = \{v_j^\beta : \psi(v_j^\beta)\}$. Assume for convenience that $i \neq j$. Then

$$f(s = t) = \begin{cases} f(\forall v_i^\alpha\, (\varphi(v_i^\beta) \leftrightarrow v_i^\alpha \in t)) & \text{if } \alpha > \beta, \\ f(\forall v_i^\alpha\, \forall v_j^\beta\, (v_i^\alpha = v_j^\beta \rightarrow (\varphi(v_i^\alpha) \leftrightarrow \psi(v_j^\beta)))) & \text{if } \alpha = \beta, \\ f(\forall v_j^\beta\, (v_j^\beta \in s \leftrightarrow \varphi(v_j^\beta))) & \text{if } \alpha < \beta; \end{cases}$$

$$f(s \in t) = \begin{cases} f(\exists v_j^\beta\, (v_j^\beta = s \wedge \psi(v_j^\beta))) & \text{if } \alpha < \beta, \\ f(\exists v_j^\beta\, (\forall v_i^\alpha\, (v_i^\alpha \in v_j^\beta \leftrightarrow \varphi(v_i^\alpha)) \wedge \psi(v_j^\beta))) & \text{if } \alpha \geq \beta. \end{cases}$$

Case 2: $\operatorname{rank}(s) = \alpha + 1$ and $\operatorname{rank}(t) = 0$. Say $s = \{v_i^\alpha : \varphi(v_i^\alpha)\}$. Put $j = i + 1$. Then

$$f(s = t) = f(\forall v_i^\alpha\, (\varphi(v_i^\alpha) \leftrightarrow v_i^\alpha \in t));$$
$$f(s \in t) = f(\exists v_j^0\, (\forall v_i^\alpha\, (v_i^\alpha \in v_j^0 \leftrightarrow \varphi(v_i^\alpha)) \wedge v_j^0 \in t)).$$

Case 3: $\operatorname{rank}(s) = 0$ and $\operatorname{rank}(t) = \beta + 1$. Say $t = \{v_j^\beta : \psi(v_j^\beta)\}$. Then

$$f(s = t) = f(\forall v_j^\beta\, (v_j^\beta \in s \leftrightarrow \psi(v_j^\beta));$$
$$f(s \in t) = f(\exists v_j^\beta\, (v_j^\beta = s \wedge \psi(v_j^\beta))).$$

Case 4: $\operatorname{rank}(s) = \operatorname{rank}(t) = 0$. Say $s = \underline{a}$ and $t = \underline{b}$ where $a, b \in u$. Then

$$f(s = t) = \begin{cases} 1 & \text{if } a = b, \\ 0 & \text{if } a \neq b; \end{cases}$$

$$f(s \in t) = \begin{cases} 1 & \text{if } a \in b, \\ 0 & \text{if } a \notin b. \end{cases}$$

This completes the definition of the valuation $f : \mathrm{S}_\gamma^u \to \{0, 1\}$. By arithmetical transfinite induction, $f$ is unique.

Let $\mathrm{T}_\gamma^u$ be the suitable tree consisting of $\langle\rangle$ plus all $\langle\varphi(v_i^\alpha)\rangle$ such that $i < \omega$, $\alpha < \gamma$, $\varphi(v_i^\alpha) \in \mathrm{F}_\gamma^u$, plus all $\langle\varphi(v_i^\alpha), t_0, \ldots, t_k\rangle$ such that $\varphi(v_i^\alpha) \in \mathrm{F}_\gamma^u$, $f(\varphi(t_0)) = 1$, and $f(t_{i+1} \in t_i) = 1$ for all $i < k$. It is straightforward to prove that $|\mathrm{T}_\gamma^u| = \mathrm{L}_\gamma^u$. This gives the existence of $\mathrm{L}_\gamma^u$, and the uniqueness is straightforward by transfinite induction on $\gamma$. (As in lemma VII.4.1, although $g$ was used to prove the existence of $\mathrm{L}_\gamma^u$, the set $\mathrm{L}_\gamma^u$ is independent of the choice of $g$.) □

THEOREM VII.4.3. *The following is provable in* $\mathsf{ATR}_0^{\mathrm{set}}$. *Let $u$ and $v$ be nonempty transitive sets.*

1. $u \cup \{u\} \subseteq \operatorname{def}(u)$.
2. $\operatorname{def}(u)$ *is transitive.*
3. $\mathrm{L}_0^u = u$; $\mathrm{L}_{\alpha+1}^u = \operatorname{def}(\mathrm{L}_\alpha^u)$.
4. $\operatorname{Lim}(\delta) \rightarrow \mathrm{L}_\delta^u = \bigcup_{\alpha<\delta} \mathrm{L}_\alpha^u$.

5. $\alpha < \beta \to \mathrm{L}^u_\alpha \in \mathrm{L}^u_\beta$.
6. $\alpha \subseteq \mathrm{L}^u_\alpha$; $\mathrm{L}^u_\alpha$ *is transitive.*
7. $\mathrm{Lim}(\delta) \to \mathrm{L}^u_\delta$ *is rudimentarily closed.*
8. $v = \mathrm{L}^u_\alpha \to \mathrm{L}^v_\beta = \mathrm{L}^u_{\alpha+\beta}$.
9. $v \in \mathrm{L}^u_\alpha \to \mathrm{L}^v_\beta \in \mathrm{L}^u_{\alpha+\beta}$.

PROOF. The proof is straightforward. □

DEFINITION VII.4.4 (the inner model $\mathrm{L}^u$). This definition is made in $\mathsf{ATR}^{\mathrm{set}}_0$. Let $u$ be a nonempty transitive set. A set $x$ is said to be *constructible from* $u$, written $x \in \mathrm{L}^u$, if $\exists\alpha\,(x \in \mathrm{L}^u_\alpha)$, i.e., $\exists\alpha\,\exists y\,(x \in y \wedge y = \mathrm{L}^u_\alpha)$.

DEFINITION VII.4.5 (relativization to $\mathrm{L}^u$). Let $\varphi$ be any formula of $\mathrm{L}_{\mathrm{set}}$. By induction on the complexity of $\varphi$ we define a formula $\varphi^{\mathrm{L}^u}$, the *relativization of* $\varphi$ *to* $\mathrm{L}^u$, as follows:

$$(x = y)^{\mathrm{L}^u} \text{ is } x = y;$$
$$(x \in y)^{\mathrm{L}^u} \text{ is } x \in y;$$
$$(\neg\varphi)^{\mathrm{L}^u} \text{ is } \neg(\varphi^{\mathrm{L}^u});$$
$$(\varphi \wedge \psi)^{\mathrm{L}^u} \text{ is } \varphi^{\mathrm{L}^u} \wedge \psi^{\mathrm{L}^u};$$
$$(\forall x\,\varphi)^{\mathrm{L}^u} \text{ is } \forall x\,(x \in \mathrm{L}^u \to \varphi^{\mathrm{L}^u}).$$

Intuitively, $\varphi^{\mathrm{L}^u}$ means that $\varphi$ is true in the transitive model $(\mathrm{L}^u, \in\restriction \mathrm{L}^u)$. We sometimes express $\varphi^{\mathrm{L}^u}$ by saying that $\mathrm{L}^u$ *satisfies* $\varphi$.

LEMMA VII.4.6. *In* $\mathsf{ATR}^{\mathrm{set}}_0$ *we have*:

1. *The formulas* $v = \mathrm{L}^u_\alpha$, $x \in \mathrm{L}^u_\alpha$, *and* $x \in \mathrm{L}^u$ *are equivalent to* $\Sigma^{\mathrm{set}}_1$ *formulas.*
2. *If* $\varphi$ *is equivalent to a* $\Sigma^{\mathrm{set}}_k$ *formula,* $0 \le k < \omega$, *then* $\varphi^{\mathrm{L}^u}$ *is equivalent to a* $\Sigma^{\mathrm{set}}_k$ *formula.*

PROOF. Part 1 is straightforward. We now deduce part 2. Using the fact that $\mathrm{L}^u$ is transitive, we see that for any $\Sigma^{\mathrm{set}}_0$ formula $\varphi$, $\varphi^{\mathrm{L}^u}$ is equivalent to $\varphi$ itself. Suppose now that $\varphi$ is $\Sigma^{\mathrm{set}}_{k+1}$. Write $\varphi$ as $\exists x\,\psi$ where $\psi$ is $\Pi^{\mathrm{set}}_k$. Then $\varphi^{\mathrm{L}^u}$ is equivalent to

$$\exists x\,(x \in \mathrm{L}^u \wedge \psi^{\mathrm{L}^u}).$$

By part 1, $x \in \mathrm{L}^u$ is equivalent to a $\Sigma^{\mathrm{set}}_1$ formula. By induction on $k$, $\psi^{\mathrm{L}^u}$ is equivalent to a $\Pi^{\mathrm{set}}_k$ formula. Hence $\varphi^{\mathrm{L}^u}$ is equivalent to a $\Sigma^{\mathrm{set}}_{k+1}$ formula. This completes the proof. □

DEFINITION VII.4.7 (absoluteness). Within $\mathsf{ATR}^{\mathrm{set}}_0$, we say that $\varphi$ *is absolute to* $\mathrm{L}^u$ if

$$\forall x_1 \cdots \forall x_m\,((x_1 \in \mathrm{L}^u \wedge \cdots \wedge x_m \in \mathrm{L}^u) \to (\varphi \leftrightarrow \varphi^{\mathrm{L}^u}))$$

holds, where $x_1, \ldots, x_m$ are the free variables of $\varphi$.

We shall sometimes write $V = L^u$ as an abbreviation for the formula

$$\forall x\,(x \in L^u).$$

THEOREM VII.4.8. *The following is provable in* $\mathsf{ATR}_0^{\mathrm{set}}$. *Let $u$ be a nonempty transitive set. The formulas $x = L_\alpha^u$, $x \in L_\alpha^u$, and $x \in L^u$ are absolute to $L^u$.*

PROOF. By $x = L_\alpha^u$ we mean of course the $\Sigma_1^{\mathrm{set}}$ formula $\exists f\,(\mathrm{Fcn}(f) \wedge \mathrm{dom}(f) = \alpha + 1 \wedge f'\alpha = x \wedge f'0 = u \wedge \forall\beta\,(\beta < \alpha \to f'\beta + 1 = \mathrm{def}(f'\beta)) \wedge \forall\delta\,((\delta \leq \alpha \wedge \mathrm{Lim}(\delta)) \to f'\delta = \bigcup f''\delta))$. Since $L^u$ is transitive, every $\Delta_0^{\mathrm{set}}$ formula is absolute to $L^u$. Using this, it is straightforward to check that each of the component formulas $\mathrm{Fcn}(w)$, $\mathrm{dom}(w) = \alpha + 1$, etc., including $w = \mathrm{def}(v)$ is absolute. It remains to show that the "constructing function" $f = f_\alpha$ is an element of $L^u$. But, by VII.4.3.7 and transfinite induction on $\alpha$, it is straightforward to check that in fact $f_\alpha \in L_{\alpha+3}^u$. Hence $x = L_\alpha^u$ is absolute. The absoluteness of $x \in L_\alpha^u$ and of $x \in L^u$ follow immediately. □

COROLLARY VII.4.9. *The following is provable in* $\mathsf{ATR}_0^{\mathrm{set}}$. *Let $u$ be a nonempty transitive set. Then $L^u$ satisfies $V = L^u$.*

PROOF. $V = L^u$ is an abbreviation for $\forall x\,(x \in L^u)$. Hence $(V = L^u)^{L^u}$ is equivalent to $\forall x\,(x \in L^u \to (x \in L^u)^{L^u})$. But by absoluteness of $x \in L^u$ this is equivalent to the tautology $\forall x\,(x \in L^u \to x \in L^u)$. □

We now turn to the Shoenfield absoluteness theorem. We shall see that the formula "$r$ is a regular relation" is, provably in $\Pi_1^1$-$\mathsf{CA}_0^{\mathrm{set}}$, absolute to $L^u$. This will be seen to imply that all $\Sigma_2^1$ formulas are absolute to $L^u$.

LEMMA VII.4.10. *The following is provable in* $\mathsf{ATR}_0^{\mathrm{set}}$. *Let $u$ be a nonempty transitive set. Let $r$ be a regular relation, and let $f$ be the collapsing function of $r$. If $r \in L^u$, then $f \in L^u$.*

PROOF. Recall from definition VII.3.8 that the collapsing function of $r$ is the unique function $f$ such that $\mathrm{dom}(f) = \mathrm{field}(r)$ and, for all $x \in \mathrm{field}(r)$,

$$f'x = f''\{y\colon \langle y, x\rangle \in r\}.$$

By the Axiom of Countability, let $g$ be an injection such that $\mathrm{dom}(g) = \mathrm{field}(r)$ and $\mathrm{rng}(g) \subseteq \omega$. Let $S$ be the suitable tree consisting of $\langle\rangle$ plus all $\langle g'x_0, \ldots, g'x_k\rangle$ such that $\forall i\,(i < k \to \langle x_{i+1}, x_i\rangle \in r)$. Let $\mathrm{KB}(S)$ be the Kleene-Brouwer ordering of $S$. By lemma V.1.3, $\mathrm{KB}(S)$ is a well ordering. Hence by Axiom Beta there is a unique function $h$ such that $\mathrm{dom}(h) = S$ and, for all $\sigma \in S$,

$$h'\sigma = h''\{\tau\colon \tau <_{\mathrm{KB}(S)} \sigma\}.$$

Put $\gamma = \mathrm{rng}(h)$. Clearly $\gamma$ is an ordinal, the order type of $\mathrm{KB}(S)$, and $h$ is the unique order isomorphism of $\mathrm{KB}(S)$ onto $\gamma$.

Let $r^*$ be the transitive closure of $r$, i.e.,

$$r^* = \{\langle y, x\rangle \colon \exists k\, \exists s\, (k \in \omega \wedge \mathrm{Fcn}(s) \wedge \mathrm{dom}(s) = k+2 \\ \wedge s'0 = x \wedge \forall i\, (i \leq k \to \langle s'i+1, s'i\rangle \in r) \wedge s'k+1 = y\}.$$

For each $x \in \mathrm{field}(r)$, put

$$r^*_x = \{x\} \cup \{y \colon \langle y, x\rangle \in r^*\}.$$

Let $\alpha$ be such that $r \in \mathrm{L}^u_\alpha$. The clearly $r^* \in \mathrm{L}^u_{\alpha+\omega}$ and $r^*_x \in \mathrm{L}^u_{\alpha+\omega}$ for all $x \in \mathrm{field}(r)$.

We claim that, for all $\beta < \gamma$ and $\sigma = \langle g'x_0, \ldots, g'x_k\rangle \in S$, if $h'\sigma \leq \beta$ then

$$f \restriction r^*_{x_k} \in \mathrm{L}^u_{\alpha+\omega\cdot(1+\beta)+5}.$$

We prove this by transfinite induction on $\beta$. Let $\sigma = \langle g'x_0, \ldots, g'x_k\rangle \in S$ be such that $h'\sigma \leq \beta$. Let $y$ be such that $\langle y, x_k\rangle \in r$. Then $\sigma^\frown\langle g'y\rangle \in S$ and $h'\sigma^\frown\langle g'y\rangle < \beta$. Hence by inductive hypothesis $f \restriction r^*_y \in \mathrm{L}^u_{\alpha+\omega\cdot(1+\beta)}$. From this and VII.4.3.6 it follows that $f \restriction r^*_x \in \mathrm{L}^u_{\alpha+\omega\cdot(1+\beta)+5}$. This proves the claim.

In particular, $f \restriction r^*_x \in \mathrm{L}^u_{\alpha+\omega\cdot(1+\gamma)}$ for all $x \in \mathrm{field}(r)$. From this it follows that $f \in \mathrm{L}^u_{\alpha+\omega\cdot(1+\gamma)+1}$. This proves lemma VII.4.10. □

LEMMA VII.4.11. *The following is provable in* $\Pi^1_1$-$\mathrm{CA}^{\mathrm{set}}_0$. *Let $u$ be a non-empty transitive set. Let $r$ be a relation which is not regular. If $r \in \mathrm{L}^u$, then there exists $v \in \mathrm{L}^u$ such that $v \neq \emptyset$ and*

$$\forall x\, (x \in v \to \exists y\, (\langle y, x\rangle \in r \wedge y \in v)). \tag{20}$$

PROOF. Reasoning in $\Pi^1_1$-$\mathrm{CA}^{\mathrm{set}}_0$, let $r \in \mathrm{L}^u$ be a relation which is not regular. By the Axiom of Countability, let $g$ be an injection such that $\mathrm{dom}(g) = \mathrm{field}(r)$ and $\mathrm{rng}(g) \subseteq \omega$. Let $T$ be the tree consisting of $\langle\rangle$ plus all $\langle g'x_0, \ldots, g'x_k\rangle$ such that $\forall i\, (i < k \to \langle x_{i+1}, x_i\rangle \in r)$. By $\Pi^1_1$ comprehension, let $W$ be the set of all $m$ such that $\langle m\rangle \in T$ and $T^{\langle m\rangle}$ is suitable. For each $x \in \mathrm{field}(r)$, put $r_x = r \restriction r^*_x$ where $r^*_x$ is as in the proof of lemma VII.4.10. Thus $g'x \in W$ if and only if $r_x$ is regular. Put

$$w = \{x \colon x \in \mathrm{field}(r) \wedge g'x \in W\}$$

and $v = \mathrm{field}(r) - w$. Thus $v = \{x \colon r_x \text{ is not regular}\}$. Since $r$ is not regular, we have $v \neq \emptyset$ and (20). It remains to show that $v \in \mathrm{L}^u$.

Let $S$ be the suitable tree consisting of $\langle\rangle$ plus all $\langle m\rangle^\frown\sigma$ such that $m \in W$ and $\sigma \in T^{\langle m\rangle}$. As in the proof of lemma VII.4.10, let $\gamma$ be the order type of $\mathrm{KB}(S)$. Let $\alpha$ be such that $r \in \mathrm{L}^u_\alpha$, and put $\beta = \alpha+\omega\cdot(1+\gamma)$. As in the proof of lemma VII.4.10, we see that for all $x \in \mathrm{field}(r)$, $r_x$ is regular if and only if

$$\exists f\, (f \in \mathrm{L}^u_{\beta+1} \wedge f \text{ is the collapsing function of } r_x).$$

Hence $v = \{x\colon r_x \text{ is not regular}\} \in \mathrm{L}^u_{\beta+2}$. This completes the proof of lemma VII.4.11. □

Theorem VII.4.12. *The following is provable in* $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$. *Let $u$ be a nonempty transitive set. Then $\mathrm{L}^u$ satisfies Axiom Beta. Moreover, for all relations $r \in \mathrm{L}^u$, we have*

$$r \text{ is regular} \leftrightarrow (r \text{ is regular})^{\mathrm{L}^u}.$$

Proof. This follows immediately from theorem VII.4.3 and lemmas VII.4.10 and VII.4.11. □

Lemma VII.4.13. *The following is provable in* $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$. *Let $u$ be a nonempty transitive set. Let $\varphi(X)$ be a $\Pi^1_1$ formula with parameters from $\mathrm{L}^u$ and no free variables other than $X$. Then we have*

$$\exists X\, \varphi(X) \to \exists X\, (X \in \mathrm{L}^u \wedge \varphi(X)).$$

Proof. We reason within $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$. By lemma V.1.4 (the Kleene normal form theorem), we can write $\varphi(X)$ in the form $\varphi(X) \equiv \forall f\, \exists n\, \neg\theta(X[n], f[n])$ where $\theta(\sigma, \tau)$ is arithmetical with parameters from $\mathrm{L}^u$ and no free variables other than $\sigma$ and $\tau$. For each $\sigma \in 2^{<\omega}$, let $T_\sigma$ be the finite tree consisting of $\langle\rangle$ plus all $\tau \in \omega^{<\omega}$ such that

(i) $\tau < \mathrm{lh}(\sigma)$ (viewing $\tau$ as an element of $\omega$); and
(ii) $\forall n\, (n \le \mathrm{lh}(\tau) \to \theta(\sigma[n], \tau[n]))$.

Given $X \in 2^\omega$, put $T_X = \bigcup_{n\in\omega} T_{X[n]}$. Thus by lemma V.1.3 we have

$$\begin{aligned}\varphi(X) &\leftrightarrow T_X \text{ is suitable}\\ &\leftrightarrow \mathrm{KB}(T_X) \text{ is a well ordering.}\end{aligned}$$

Fix $X_0 \in 2^\omega$ such that $\varphi(X_0)$ holds. Then $\mathrm{KB}(T_{X_0})$ is a well ordering, so by Axiom Beta let $\alpha_0$ be the ordinal which is the order type of $\mathrm{KB}(T_{X_0})$, and let $g_0$ be the unique order isomorphism of $\mathrm{KB}(T_{X_0})$ onto $\alpha_0$. Thus $g_0$ is an injection, $\mathrm{dom}(g_0) = T_{X_0}$, $\mathrm{rng}(g_0) = \alpha_0$, and

$$g_0'\tau_1 < g_0'\tau_2 \leftrightarrow \tau_1 <_{\mathrm{KB}(T_{X_0})} \tau_2$$

for all $\tau_1, \tau_2 \in T_{X_0}$.

Let $d$ be the set of all ordered pairs $\langle\sigma, s\rangle$ such that $\sigma \in 2^{<\omega}$, $\mathrm{Fcn}(s)$, $\mathrm{dom}(s) = T_\sigma$, $\mathrm{rng}(s) \subseteq \alpha_0$, and

$$s'\tau_1 < s'\tau_2 \leftrightarrow \tau_1 <_{\mathrm{KB}(T_\sigma)} \tau_2$$

for all $\tau_1, \tau_2 \in T_\sigma$. Let $r$ be the set of all $\langle\langle\sigma', s'\rangle, \langle\sigma, s\rangle\rangle \in d \times d$ such that $\sigma \subseteq \sigma'$, $\sigma \ne \sigma'$, and $s \subseteq s'$. Since $\alpha_0 \in \mathrm{L}^u$, we have $d \in \mathrm{L}^u$ and $r \in \mathrm{L}^u$.

Let $v_0$ be the set of all ordered pairs $\langle X_0[n], g_0{\restriction}T_{X_0}\rangle$, $n \in \omega$. Then clearly $v_0 \ne \emptyset$ and

$$\forall x\, (x \in v_0 \to \exists y\, (y \in v_0 \wedge \langle y, x\rangle \in r)).$$

Hence $r$ is not regular. Hence by lemma VII.4.11 there exists $v \in \mathrm{L}^u$ such that $v \neq \emptyset$ and

$$\forall x\,(x \in v \to \exists y\,(\langle y, x\rangle \in r \wedge y \in v)).$$

Since $d = \mathrm{field}(r)$ is well ordered in $\mathrm{L}^u$, we can find a sequence $\langle\langle \sigma_n, s_n\rangle : n < \omega\rangle \in \mathrm{L}^u$ such that $\langle \sigma_n, s_n\rangle \in v$ and $\langle\langle \sigma_{n+1}, s_{n+1}\rangle, \langle \sigma_n, s_n\rangle\rangle \in r$ for all $n < \omega$. Putting $X = \bigcup_{n\in\omega} \sigma_n$ and $g = \bigcup_{n\in\omega} s_n$, we see that $X \in 2^\omega$, $\mathrm{dom}(g) = T_X$, $\mathrm{rng}(g) \subseteq \alpha_0$, and

$$g'\tau_1 < g'\tau_2 \leftrightarrow \tau_1 <_{\mathrm{KB}(T_X)} \tau_2$$

for all $\tau_1, \tau_2 \in T_X$. Hence $T_X$ is suitable, i.e., $\varphi(X)$ holds. Also $X \in \mathrm{L}^u$ by construction. This completes the proof of lemma VII.4.13. □

The next theorem is our formalized version of the Shoenfield absoluteness theorem within $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$. It will be applied in the next section to prove conservation results.

THEOREM VII.4.14 (Shoenfield absoluteness in $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$). *The following is provable in* $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$. *Let $u$ be a nonempty transitive set. Let $\varphi$ be any $\Sigma^1_2$ sentence with parameters from* $\mathrm{L}^u$. *Then $\varphi \leftrightarrow \varphi^{\mathrm{L}^u}$, i.e., $\varphi$ is absolute to* $\mathrm{L}^u$.

PROOF. This is an immediate consequence of lemma VII.4.13. □

COROLLARY VII.4.15. *The following is provable in* $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$. *Let $u$ be a nonempty transitive set. The transitive model* $\mathrm{L}^u$ *satisfies* $\mathrm{V} = \mathrm{L}^u$ *plus all axioms of* $\Pi^1_1$-$\mathsf{CA}^{\mathrm{set}}_0$ *except possibly the Axiom of Countability.*

PROOF. By corollary VII.4.9 and theorems VII.4.3 and VII.4.12, $\mathrm{L}^u$ satisfies $\mathrm{V} = \mathrm{L}^u$ plus $\mathsf{ATR}^{\mathrm{set}}_0$ except possibly for the Axiom of Countability. It remains to show that $\mathrm{L}^u$ satisfies $\Pi^1_1$-$\mathsf{CA}_0$. By theorem VII.1.12 it suffices to prove that $\mathrm{L}^u$ is closed under hyperjump. Let $X \in \mathrm{L}^u$, $X \subseteq \omega$ be given. By $\Pi^1_1$-$\mathsf{CA}_0$ we have $\exists Y\,(Y = \mathrm{HJ}(X))$. This is $\Sigma^1_2$ so by the Shoenfield absoluteness theorem VII.4.14, there exists $Y \in \mathrm{L}^u$ such that $\mathrm{L}^u$ satisfies $Y = \mathrm{HJ}(X)$. By another application of VII.4.14 it follows that $Y = \mathrm{HJ}(X)$. This completes the proof. □

EXERCISE VII.4.16. Show that the following is provable in $\Pi^1_1$-$\mathsf{TR}^{\mathrm{set}}_0$. Let $u$ be a nonempty transitive set. Then $\mathrm{L}^u$ satisfies $\mathrm{V} = \mathrm{L}^u$ plus all axioms of $\Pi^1_1$-$\mathsf{TR}^{\mathrm{set}}_0$ except possibly the Axiom of Countability.

REMARKS VII.4.17. Roughly speaking, the content of corollary VII.4.15 is that $\Pi^1_1$-$\mathsf{CA}_0$ proves its own relativization to the inner model $\mathrm{L}^u$. Exercise VII.4.16 gives the same result for $\Pi^1_1$-$\mathsf{TR}_0$. In §VII.5 below, we shall obtain a similar result for stronger systems $\Delta^1_2$-$\mathsf{CA}_0$, $\Pi^1_2$-$\mathsf{CA}_0$, $\Pi^1_2$-$\mathsf{TR}_0$, $\Delta^1_3$-$\mathsf{CA}_0$, $\Pi^1_3$-$\mathsf{CA}_0$, etc.

The phrase "except possibly the Axiom of Countability" cannot be dropped from corollary VII.4.15 or exercise VII.4.16. Indeed, Feferman and Lévy have exhibited a transitive model of $\Pi^1_\infty$-$\mathsf{CA}^{\mathrm{set}}_0$ (see definition VII.4.33 below) in which, for all nonempty transitive sets $u$,

the Axiom of Countability fails in $\mathrm{L}^u$. The transitive model exhibited by Feferman and Lévy is $M_{\mathrm{set}}$ where $M$ is as in remark VII.6.3 below.

In order to restore the Axiom of Countability, we shall now pass to a smaller inner model $\mathrm{HCL}(X)$, where $X \subseteq \omega$. See definition VII.4.22 and theorem VII.4.27 below. Some of our results about $\mathrm{HCL}(X)$ will also be of use in §VII.5.

Definition VII.4.18. Within $\mathsf{ATR}_0^{\mathrm{set}}$ we make the following definitions.

1. A *linear ordering* is a relation $\prec$ such that, writing $y \prec x$ for $\langle y, x\rangle \in \prec$, one has
   (i) $\forall x\, \forall y\, ((x \in \mathrm{field}(\prec) \wedge y \in \mathrm{field}(\prec)) \rightarrow (x \prec y \vee x = y \vee y \prec x))$;
   (ii) $\forall x\, \forall y\, \forall z\, ((z \prec y \wedge y \prec x) \rightarrow z \prec x)$; and
   (iii) $\neg \exists x\, (x \prec x)$.
2. If $\prec$ and $\prec^1$ are linear orderings, we say that $\prec$ is an initial segment of $\prec^1$ if $\prec = \prec^1 \restriction \mathrm{field}(\prec)$. By definition VII.3.2.14 this implies
$$\forall x\, \forall y\, ((y \prec^1 x \wedge x \in \mathrm{field}(\prec)) \rightarrow y \in \mathrm{field}(\prec)).$$
3. A *linear ordering of* $u$ is a linear ordering $\prec$ such that $\mathrm{field}(\prec) = u$.
4. A *well ordering* of $u$ is a linear ordering of $u$ which is regular.

Lemma VII.4.19. *Within* $\mathsf{ATR}_0^{\mathrm{set}}$, *let* $u$ *be a nonempty transitive set*.

1. *Given a well ordering* $\prec$ *of* $u$, *we can canonically define a well ordering* $\prec^*$ *of* $\mathrm{def}(u)$. *Moreover* $\prec$ *is an initial segment of* $\prec^*$.
2. *Given a well ordering* $<_0$ *of* $u$, *we can associate to each ordinal* $\alpha$ *a canonically defined well ordering* $<_\alpha$ *of* $\mathrm{L}^u_\alpha$. *Moreover, for all* $\beta < \alpha$, $<_\beta$ *is an initial segment of* $<_\alpha$.
3. *The definitions of* $\prec^*$ *and* $<_\alpha$ *are absolute to* $\mathrm{L}^u$ (*provided* $\prec$ *and* $<_0$ *belong to* $\mathrm{L}^u$).

Proof. This is essentially Gödel's argument for the axiom of choice.

To prove part 1, let $\mathrm{F}_u$ be the set of formulas of $\mathrm{L}_{\mathrm{set}}$ with parameters from $u$ and exactly one free variable. The given well ordering $\prec$ of $u$ canonically induces a well ordering $\prec^F$ of $\mathrm{F}_u$. For all $v \in \mathrm{def}(u)$, let $h'v$ be the $\prec^F$-least formula $\varphi(x) \in \mathrm{F}_u$ such that
$$v = \{x\colon x \in u \wedge \langle u, \in \restriction u\rangle \models \varphi(x)\}.$$
For $v \in \mathrm{def}(u)$ and $w \in \mathrm{def}(u)$, put $w \prec^* v$ if and only if either

(i) $w \in u \wedge v \in u \wedge w \prec v$, or
(ii) $w \in u \wedge v \in \mathrm{def}(u) - u$, or
(iii) $w \in \mathrm{def}(u) - u \wedge v \in \mathrm{def}(u) - u \wedge h'w \prec^F h'v$.

Clearly $\prec^*$ has the desired properties.

For part 2, $<_\alpha$ is defined uniquely so that

$$\exists f\,(\mathrm{Fcn}(f) \wedge \mathrm{dom}(f) = \alpha + 1 \wedge f'\alpha =<_\alpha \wedge f'0 =<_0 \wedge \forall\beta\,(\beta < \alpha \to f'\beta + 1 = (f'\beta)^*) \wedge \forall\delta\,((\delta \leq \alpha \wedge \mathrm{Lim}(\delta)) \to f'\delta = \bigcup f''\delta)).$$

Here $*$ is as in part 1. The proof of part 3 is straightforward. □

DEFINITION VII.4.20. The following definition is made within $\mathsf{ATR}_0^{\mathrm{set}}$. Given $X \subseteq \omega$, note that $\omega \cup \{X\}$ is a nonempty transitive set and put $\mathrm{L}_\alpha(X) = \mathrm{L}_\alpha^{\omega\cup\{X\}}$ and $\mathrm{L}(X) = \mathrm{L}^{\omega\cup\{X\}}$. Let $<_0^{\mathrm{L}(X)}$ be the well ordering of $\omega \cup \{X\}$ given by

$$<_0^{\mathrm{L}(X)} = \begin{cases} \in\restriction\omega & \text{if } X \in \omega, \\ (\in\restriction\omega) \cup (\omega \times \{X\}) & \text{otherwise.} \end{cases}$$

Then for all ordinals $\alpha$, let $<_\alpha^{\mathrm{L}(X)}$ be the canonically associated well ordering of $\mathrm{L}_\alpha(X)$ as in lemma VII.4.19. For $u \in \mathrm{L}(X)$ and $v \in \mathrm{L}(X)$, put $v <^{\mathrm{L}(X)} u$ if and only if $\exists\alpha\,(v <_\alpha^{\mathrm{L}(X)} u)$. We refer to $<^{\mathrm{L}(X)}$ as the *canonical well ordering* of $\mathrm{L}(X)$.

LEMMA VII.4.21. *Provably in* $\mathsf{ATR}_0^{\mathrm{set}}$, *the formulas* $u \in \mathrm{L}(X)$, $v <^{\mathrm{L}(X)} u$ *and* $w = \{v\colon v <^{\mathrm{L}(X)} u\}$ *are* $\Sigma_1^{\mathrm{set}}$ *and absolute to* $\mathrm{L}(X)$.

PROOF. This is similar to the proof of lemma VII.4.6.1 and theorem VII.4.8. □

DEFINITION VII.4.22 (the inner model $\mathrm{HCL}(X)$). Within $\mathsf{ATR}_0^{\mathrm{set}}$, assume $X \subseteq \omega$. We write $u \in \mathrm{HCL}(X)$ to mean that $u$ is *hereditarily constructibly countable* from $X$, i.e.,

$$\exists f\,(f \in \mathrm{L}(X) \wedge \mathrm{Fcn}(f) \wedge \mathrm{dom}(f) = \omega \wedge u \subseteq \mathrm{rng}(f) \wedge \mathrm{Trans}(\mathrm{rng}(f))).$$

If $\varphi$ is any formula of $\mathrm{L}_{\mathrm{set}}$, the *relativization of* $\varphi$ *to* $\mathrm{HCL}(X)$ is written $\varphi^{\mathrm{HCL}(X)}$ and is defined in the obvious way, exactly as for $\varphi^{\mathrm{L}(X)}$ (definition VII.4.5). We sometimes express $\varphi^{\mathrm{HCL}(X)}$ by saying that $\mathrm{HCL}(X)$ *satisfies* $\varphi$.

Obviously $\mathrm{HCL}(X)$ is a transitive submodel of $\mathrm{L}(X)$, i.e., $\forall u\,(u \in \mathrm{HCL}(X) \to u \in \mathrm{L}(X))$ and $\forall u\,\forall v\,((v \in u \wedge u \in \mathrm{HCL}(X)) \to v \in \mathrm{HCL}(X))$. In addition we have $\forall u\,\forall v\,((u \in \mathrm{HCL}(X) \wedge v \subseteq u \wedge v \in \mathrm{L}(X)) \to v \in \mathrm{HCL}(X))$.

LEMMA VII.4.23. *Provably in* $\mathsf{ATR}_0^{\mathrm{set}}$ *we have*:

1. *The formula* $u \in \mathrm{HCL}(X)$ *is equivalent to a* $\Sigma_1^{\mathrm{set}}$ *formula.*
2. *If* $\varphi$ *is any* $\Sigma_k^{\mathrm{set}}$ *formula,* $0 \leq k < \omega$, *then* $\varphi^{\mathrm{HCL}(X)}$ *is equivalent to a* $\Sigma_k^{\mathrm{set}}$ *formula.*

PROOF. This is exactly like the proof of lemma VII.4.6. □

Definition VII.4.24. We say that $\varphi$ *is absolute to* $\mathrm{HCL}(X)$ if

$$\forall x_1 \cdots \forall x_m \left((x_1 \in \mathrm{HCL}(X) \wedge \cdots \wedge x_m \in \mathrm{HCL}(X)) \rightarrow (\varphi \leftrightarrow \varphi^{\mathrm{HCL}(X)})\right)$$

holds, where $x_1, \ldots, x_m$ are the free variables of $\varphi$.

We sometimes write $\mathrm{V} = \mathrm{HCL}(X)$ as an abbreviation for $\forall u\,(u \in \mathrm{HCL}(X))$.

Lemma VII.4.25. *Within* $\mathsf{ATR}_0^{\mathrm{set}}$, *assume* $X \subseteq \omega$. *If* $\varphi$ *is any* $\Sigma_1^{\mathrm{set}}$ *sentence with parameters from* $\mathrm{HCL}(X)$, *we have*

$$\varphi^{\mathrm{L}(X)} \leftrightarrow \varphi^{\mathrm{HCL}(X)}.$$

Proof. Since $\mathrm{HCL}(X) \subseteq_{\mathrm{trans}} \mathrm{L}(X)$, it is clear $\varphi^{\mathrm{HCL}(X)}$ implies $\varphi^{\mathrm{L}(X)}$. We shall prove the converse. This will be essentially Gödel's argument for the continuum hypothesis.

Assume $\varphi^{\mathrm{L}(X)}$. The parameters of $\varphi$ belong to $\mathrm{HCL}(X)$, so let $u \in \mathrm{HCL}(X)$ be transitive and contain these parameters. Write $\varphi$ as $\exists x\, \theta(x)$ where $\theta(x)$ is $\Delta_0^{\mathrm{set}}$ with the same parameters as $\varphi$. Fix $z \in \mathrm{L}(X)$ such that $\theta(z)$ holds in $\mathrm{L}(X)$. Let $\delta$ be a limit ordinal such that $u \subseteq \mathrm{L}_\delta(X)$ and $z \in \mathrm{L}_\delta(X)$. Hence $\theta(z)$ holds in $\mathrm{L}_\delta(X)$.

Let $v$ be the smallest subset of $\mathrm{L}_\delta(X)$ such that $u \subseteq v$, $z \in v$, and $v$ is closed under definability in the language $=, \in, <$ over the model

$$\langle \mathrm{L}_\delta(X), \in \restriction \mathrm{L}_\delta(X), <_\delta^{\mathrm{L}(X)} \rangle.$$

Since $<_\delta^{\mathrm{L}(X)}$ is a well ordering of $\mathrm{L}_\delta(X)$, $v$ is an elementary submodel of $\langle \mathrm{L}_\delta(X), \in \restriction \mathrm{L}_\delta(X) \rangle$. In particular $v$ satisfies $\theta(z)$. Also, since $<_\delta^{\mathrm{L}(X)} \in \mathrm{L}(X)$ and $u$ is countable in $\mathrm{L}(X)$, it follows that $v$ is countable in $\mathrm{L}(X)$, i.e., there exists a function $g \in \mathrm{L}(X)$ such that $\mathrm{dom}(g) = \omega$ and $\mathrm{rng}(g) = v$.

Let $f$ be the collapsing function of $v$, i.e., $f$ is the unique function such that $\mathrm{dom}(f) = v$ and

$$f'x = f''\{y : y \in v \wedge y \in x\}$$

for all $x \in v$. Put $w = \mathrm{rng}(f)$. Thus $w$ is transitive and $f$ is the unique $\in$-isomorphism of $v$ onto $w$. By lemma VII.4.10 we have $f \in \mathrm{L}(X)$, hence $fg \in \mathrm{L}(X)$. Since $\mathrm{dom}(fg) = \omega$ and $\mathrm{rng}(fg) = w$, it follows that $w \in \mathrm{HCL}(X)$.

The transitivity of $u$ implies that $y = f'y \in w$ for all $y \in u$. In particular this holds for all of the parameters $y$ of $\theta(x)$. Therefore $\langle w, \in \restriction w \rangle$ satisfies $\theta(f'z)$. Since $w \subseteq_{\mathrm{trans}} \mathrm{HCL}(X)$, we see that $\mathrm{HCL}(X)$ satisfies $\theta(f'z)$. Thus $\mathrm{HCL}(X)$ satisfies $\exists x\, \theta(x)$, i.e., $\varphi$.

This completes the proof of lemma VII.4.25. □

Lemma VII.4.26. *The following is provable in* $\mathsf{ATR}_0^{\mathrm{set}}$. *For* $X \subseteq \omega$, *the formulas* $u \in \mathrm{HCL}(X)$, $u = \mathrm{L}_\alpha(X)$, $v <^{\mathrm{L}(X)} u$, *and* $w = \{v : v <^{\mathrm{L}(X)} u\}$ *are* $\Sigma_1^{\mathrm{set}}$ *and absolute to* $\mathrm{HCL}(X)$. *In particular,* $\mathrm{HCL}(X)$ *satisfies* $\mathrm{V} = \mathrm{HCL}(X)$.

PROOF. By theorem VII.4.8 and lemmas VII.4.6.1, VII.4.21, and VII.4.23.1, the mentioned formulas are $\Sigma^{\text{set}}_1$ and absolute to $\mathrm{L}(X)$. Hence by lemma VII.4.25 they are absolute to $\mathrm{HCL}(X)$. □

THEOREM VII.4.27. *The following is provable in* $\Pi^1_1$-$\mathsf{CA}^{\text{set}}_0$. *Assume* $X \subseteq \omega$. *Then*:

1. $\mathrm{HCL}(X)$ *satisfies* $\mathrm{V} = \mathrm{HCL}(X)$ *plus all axioms of* $\Pi^1_1$-$\mathsf{CA}^{\text{set}}_0$.
2. *All* $\Sigma^1_2$ *and* $\Sigma^{\text{set}}_1$ *formulas are absolute to* $\mathrm{HCL}(X)$. *In other words,* $\varphi \leftrightarrow \varphi^{\mathrm{HCL}(X)}$ *holds for all* $\Sigma^1_2$ *or* $\Sigma^{\text{set}}_1$ *sentences* $\varphi$ *with parameters from* $\mathrm{HCL}(X)$.

PROOF. Part 1 follows from corollary VII.4.15 and lemma VII.4.26. Part 2 follows from part 1, theorem VII.4.14 (absoluteness of $\Sigma^1_2$ formulas) and theorem VII.3.24 (equivalence of $\Sigma^1_2$ with $\Sigma^{\text{set}}_1$). □

EXERCISE VII.4.28. Within $\mathsf{ATR}^{\text{set}}_0$, assuming $X \subseteq \omega$, show that $\mathrm{HCL}(X)$ satisfies $\mathrm{V} = \mathrm{HCL}(X)$ plus all axioms of $\mathsf{ATR}^{\text{set}}_0$ except possibly Axiom Beta.

EXERCISE VII.4.29. Exhibit a transitive model of $\mathsf{ATR}^{\text{set}}_0$ in which $\mathrm{HCL}(\emptyset)$ does not satisfy Axiom Beta. Show that $\mathsf{ATR}^{\text{set}}_0$ proves the following: $\Pi^1_1$-$\mathsf{CA}_0$ if and only if

$$\forall X\,(X \subseteq \omega \rightarrow (\text{Axiom Beta})^{\mathrm{HCL}(X)}).$$

EXERCISE VII.4.30. Exhibit a transitive model of $\mathsf{ATR}^{\text{set}}_0$ in which not all $\Sigma^1_1$ sentences are absolute to $\mathrm{HCL}(\emptyset)$. Show that $\mathsf{ATR}^{\text{set}}_0$ proves the following: $\Pi^1_1$-$\mathsf{CA}_0$ if and only if all $\Sigma^1_1$ formulas are absolute to $\mathrm{HCL}(X)$ for all $X \subseteq \omega$.

EXERCISE VII.4.31. Within $\mathsf{ATR}^{\text{set}}_0$, assuming $X \subseteq \omega$, show that if the hyperjump $Y = \mathrm{HJ}(X)$ exists then $Y \in \mathrm{HCL}(X)$ and $\mathrm{HCL}(X)$ satisfies $Y = \mathrm{HJ}(X)$.

EXERCISE VII.4.32. Let $\varphi(X, Y)$ be a $\Pi^1_1$ formula with no free variables other than $X$ and $Y$. Prove in $\mathsf{ATR}^{\text{set}}_0$ that for all $X \subseteq \omega$, if there exists $Y$ such that $\varphi(X, Y)$ holds and $\mathrm{HJ}(X \oplus Y)$ exists, then there exists $Y \in \mathrm{HCL}(X)$ such that $\varphi(X, Y)$ holds. (This is a refinement of lemma VII.4.13.)

We end this section with a theorem concerning the special situation when $\mathrm{HCL}(X)$ is not all of $\mathrm{L}(X)$. The conclusion in this case is rather strong.

DEFINITION VII.4.33. $\Pi^1_\infty$-$\mathsf{CA}^{\text{set}}_0$ is the theory in $\mathrm{L}_{\text{set}}$ which consists of $\mathsf{ATR}^{\text{set}}_0$ plus the *full comprehension scheme*:

$$\forall u\,\exists v\,\forall x\,(x \in v \leftrightarrow (x \in u \wedge \varphi(x)))$$

where $\varphi(x)$ is any formula of $\mathrm{L}_{\text{set}}$ in which $v$ does not occur freely. (See also lemma VII.5.3.)

Theorem VII.4.34. *The following is provable in* $\mathsf{ATR}_0^{\mathrm{set}}$. *Assume* $X \subseteq \omega$. *Suppose that* $\mathrm{HCL}(X) \neq \mathrm{L}(X)$. *Then*:

1. $\mathrm{HCL}(X) = \mathrm{L}_\delta(X)$ *for a certain limit ordinal* $\delta$.
2. $\mathrm{HCL}(X)$ *satisfies* $\mathrm{V} = \mathrm{HCL}(X)$ *plus all axioms of* $\Pi^1_\infty$-$\mathsf{CA}_0^{\mathrm{set}}$.
3. $\mathrm{HCL}(X)$ *satisfies Axiom Beta. Moreover, for all relations* $r \in \mathrm{HCL}(X)$, *we have*

$$r \text{ is regular} \leftrightarrow (r \text{ is regular})^{\mathrm{HCL}(X)}.$$

4. $\mathrm{HCL}(X)$ *is closed under hyperjump. All* $\Sigma^1_1$ *formulas are absolute to* $\mathrm{HCL}(X)$.

Proof. By lemmas VII.4.25 and VII.4.26, we have $u \in \mathrm{HCL}(X)$ if and only if $\exists \alpha\, (u \in \mathrm{L}_\alpha(X) \wedge \mathrm{L}_\alpha(X) \in \mathrm{HCL}(X))$. If $\mathrm{HCL}(X) \neq \mathrm{L}(X)$, it follows that there exists an ordinal $\gamma$ such that $\mathrm{L}_\gamma(X) \notin \mathrm{HCL}(X)$. Hence $\mathrm{HCL}(X) \subseteq \mathrm{L}_\gamma(X)$. Let $\delta$ be the set of all $\alpha < \gamma$ such that

$$\exists f\, (f \in \mathrm{L}_\gamma(X) \wedge \mathrm{Fcn}(f) \wedge \mathrm{dom}(f) = \omega \wedge \mathrm{rng}(f) = \mathrm{L}_\alpha(X)).$$

Then clearly $\delta$ is a limit ordinal and $\mathrm{L}_\delta(X) = \mathrm{HCL}(X)$. This proves part 1. (It can be shown that $\delta$ is the smallest uncountable ordinal of $\mathrm{L}(X)$.)

For part 2, let $\varphi(x)$ be a formula of $\mathrm{L}_{\mathrm{set}}$ with parameters from $\mathrm{HCL}(X)$ and no free variables other than $x$. Given $u \in \mathrm{HCL}(X) = L_\delta(X)$, put

$$v = \{x\colon x \in u \wedge \langle \mathrm{L}_\delta(X), \in \restriction \mathrm{L}_\delta(X)\rangle \models \varphi(x)\}.$$

Thus $v \in \mathrm{L}_{\delta+1}(X)$. Since $v \subseteq u$ and $u \in \mathrm{HCL}(X)$, it follows trivially that $v \in \mathrm{HCL}(X)$. Then clearly $\mathrm{HCL}(X) = \mathrm{L}_\delta(X)$ satisfies $\forall x\, (x \in v \leftrightarrow (x \in u \wedge \varphi(x)))$. This shows that $\mathrm{HCL}(X)$ is a model of full comprehension.

By lemma VII.4.26, $\mathrm{HCL}(X)$ satisfies $\mathrm{V} = \mathrm{HCL}(X)$. By theorem VII.4.3.7, $\mathrm{HCL}(X) = \mathrm{L}_\delta(X)$ satisfies $\mathsf{B}_0^{\mathrm{set}}$. It is obvious that $\mathrm{HCL}(X)$ satisfies the Axioms of Regularity and Countability. It remains to prove that $\mathrm{HCL}(X)$ satisfies Axiom Beta.

Let $r \in \mathrm{HCL}(X)$ be a relation. If $r$ is regular, lemma VII.4.10 implies that the collapsing function of $r$ belongs to $\mathrm{HCL}(X)$. Suppose now that $r$ is not regular. We shall use the notation $r_x$ which was introduced in the proof of lemma VII.4.11. Let $w$ be the set of $x \in \mathrm{field}(r)$ such that the collapsing function of $r_x$ is an element of $\mathrm{HCL}(X)$. Since $\mathrm{HCL}(X)$ is a transitive model of full comprehension, $w \in \mathrm{HCL}(X)$. Put $v = \mathrm{field}(r) - w$. Then $v \in \mathrm{HCL}(X)$ and, since $r$ is not regular, $v \neq \emptyset$. If $x \in \mathrm{field}(r)$ and $\forall y\, (\langle y, x\rangle \in r \to y \in w)$, then $r_x$ is regular, hence by lemma VII.4.10 $x \in w$. Hence $\forall x\, (x \in v \to \exists y\, (\langle y, x\rangle \in r \wedge y \in v))$. Thus $(r \text{ is not regular})^{\mathrm{HCL}(X)}$.

Combining these observations, we see that $\mathrm{HCL}(X)$ satisfies Axiom Beta. This completes the proof of part 2 and also proves part 3.

To prove part 4, let $\varphi$ be a $\Sigma^1_1$ sentence with parameters from $\mathrm{HCL}(X)$. By the Kleene normal form theorem V.1.4, we can write $\varphi$ as $\exists f\, \forall n\, \theta(f[n])$ where $\theta(\tau)$ is arithmetical with parameters from $\mathrm{HCL}(X)$. Let $r$ be the set of all $\langle \tau^\frown \langle k \rangle, \tau \rangle$ such that $\forall n\, (n \leq \mathrm{lh}(\tau) \to \theta(\tau[n]))$. Using part 3 we see that

$$\begin{aligned} \varphi &\leftrightarrow r \text{ is not regular} \\ &\leftrightarrow (r \text{ is not regular})^{\mathrm{HCL}(X)} \\ &\leftrightarrow \varphi^{\mathrm{HCL}(X)}. \end{aligned}$$

This shows that all $\Sigma^1_1$ formulas are absolute to $\mathrm{HCL}(X)$. In other words, $\mathrm{HCL}(X)$ is a $\beta$-model. Also, from part 2 it follows a fortiori that $\mathrm{HCL}(X)$ satisfies $\Pi^1_1$-$\mathsf{CA}_0$. Hence by theorem VII.1.12 $\mathrm{HCL}(X)$ is closed under hyperjump.

This completes the proof of theorem VII.4.34. □

EXERCISE VII.4.35. Exhibit a transitive model of $\mathsf{ATR}^{\mathrm{set}}_0$ in which $\mathrm{HCL}(\emptyset) \neq \mathrm{L}(\emptyset)$, yet not all $\Sigma^1_2$ or $\Sigma^{\mathrm{set}}_1$ sentences are absolute to $\mathrm{HCL}(\emptyset)$.

**Notes for §VII.4.** Gödel's original papers [95, 96] on constructible sets are still worth reading. Gödel's subsequent detailed treatment [97] is much less accessible. For further information on constructible sets, see Jensen [131] or any good textbook of axiomatic set theory, e.g., Jech [130]. The original Shoenfield absoluteness theorem is due to Shoenfield [221] and is closely related to Kondo's theorem (§VI.2). Our observation that the Shoenfield absoluteness theorem is provable in $\Pi^1_1$-$\mathsf{CA}_0$ (theorem VII.4.14) was inspired by Jensen/Karp [132] and Barwise/Fisher [14] (see also Barwise [13, §V.8]). Our theorem VII.4.27.2 on $\Sigma^{\mathrm{set}}_1$ absoluteness is similar to a result of Lévy [162, theorem 43].

## VII.5. Strong Comprehension Schemes

In this and the next two sections, we study $\beta$-models of certain subsystems of second order arithmetic which are stronger than $\Pi^1_1$-$\mathsf{CA}_0$. We rely on the set-theoretic results of the previous two sections.

DEFINITION VII.5.1 (comprehension schemes). Assume $0 < k < \omega$.

1. $\Pi^1_k$-$\mathsf{CA}_0$ is the subsystem of $\mathsf{Z}_2$ which consists of $\mathsf{ACA}_0$ plus the scheme of $\Pi^1_k$ *comprehension*:
$$\exists X\, \forall n\, (n \in X \leftrightarrow \psi(n))$$
where $\psi(n)$ is any $\Pi^1_k$ formula in which $X$ does not occur freely.
2. $\Delta^1_k$-$\mathsf{CA}_0$ is the subsystem of $\mathsf{Z}_2$ which consists of $\mathsf{ACA}_0$ plus the scheme of $\Delta^1_k$ *comprehension*:
$$\forall n\, (\varphi(n) \leftrightarrow \psi(n)) \to \exists X\, \forall n\, (n \in X \leftrightarrow \psi(n))$$

where $\varphi(n)$ is any $\Sigma^1_k$ formula and $\psi(n)$ is any $\Pi^1_k$ formula in which $X$ does not occur freely.

3. $\Pi^1_\infty\text{-}\mathsf{CA}_0 = \bigcup_{k<\omega} \Pi^1_k\text{-}\mathsf{CA}_0$.

Remarks VII.5.2. Obviously

$$\Delta^1_k\text{-}\mathsf{CA}_0 \subseteq \Pi^1_k\text{-}\mathsf{CA}_0 \subseteq \Delta^1_{k+1}\text{-}\mathsf{CA}_0$$

for all $k$, $0 \leq k < \omega$. We shall see later that all of these inclusions are proper except for the triviality $\mathsf{ACA}_0 = \Delta^1_0\text{-}\mathsf{CA}_0 = \Pi^1_0\text{-}\mathsf{CA}_0$. The development of mathematics within $\mathsf{ACA}_0$ has been discussed in chapter III. By theorem V.5.1 we have

$$\Delta^1_1\text{-}\mathsf{CA}_0 \subseteq \mathsf{ATR}_0 \subseteq \Pi^1_1\text{-}\mathsf{CA}_0.$$

Further results on models of $\mathsf{ACA}_0$ and $\Delta^1_1\text{-}\mathsf{CA}_0$ will be presented in chapters VIII and IX. The development of mathematics within $\Pi^1_1\text{-}\mathsf{CA}_0$ has been discussed in chapter VI. Models of $\Pi^1_1\text{-}\mathsf{CA}_0$ have been discussed in §§VII.1 and VII.4 in the present chapter. Models of $\Pi^1_{k+1}\text{-}\mathsf{CA}_0$ and $\Delta^1_{k+2}\text{-}\mathsf{CA}_0$ are the principal topic of this and the next two sections. Further results on models of $\Pi^1_{k+1}\text{-}\mathsf{CA}_0$ and $\Delta^1_{k+2}\text{-}\mathsf{CA}_0$ will be presented in chapters VIII and IX.

In order to prove theorems about models of $\Pi^1_{k+1}\text{-}\mathsf{CA}_0$ and $\Delta^1_{k+2}\text{-}\mathsf{CA}_0$, it will be convenient to work with the set-theoretic counterparts of these theories. Recall that to each $\mathrm{L}_2$-theory $T_0 \supseteq \mathsf{ATR}_0$, we have associated a set-theoretic counterpart $T_0^{\mathrm{set}}$ consisting of $\mathsf{ATR}_0^{\mathrm{set}}$ plus $T_0$. Thus $T_0^{\mathrm{set}}$ is a theory in the language $\mathrm{L}_{\mathrm{set}}$ and proves the same $\mathrm{L}_2$-sentences as $T_0$ (theorem VII.3.34). The purpose of the following lemma is to identify each of $\Pi^1_{k+2}\text{-}\mathsf{CA}_0^{\mathrm{set}}$ and $\Delta^1_{k+2}\text{-}\mathsf{CA}_0^{\mathrm{set}}$.

Lemma VII.5.3. *Assume* $0 \leq k < \omega$. *Over* $\mathsf{ATR}_0^{\mathrm{set}}$ *we have*:

1. $\Pi^1_{k+2}\text{-}\mathsf{CA}_0$ *is equivalent to the scheme of* $\Pi^{\mathrm{set}}_{k+1}$ comprehension:

$$\forall u\, \exists v\, \forall x\, (x \in v \leftrightarrow (x \in u \wedge \psi(x)))$$

*where* $\psi(x)$ *is any* $\Pi^{\mathrm{set}}_{k+1}$ *formula in which* $v$ *does not occur freely.*

2. $\Delta^1_{k+2}\text{-}\mathsf{CA}_0$ *is equivalent to the scheme of* $\Delta^{\mathrm{set}}_{k+1}$ comprehension:

$$\forall x\, (\varphi(x) \leftrightarrow \psi(x)) \rightarrow \forall u\, \exists v\, \forall x\, (x \in v \leftrightarrow (x \in u \wedge \psi(x)))$$

*where* $\varphi(x)$ *is any* $\Sigma^{\mathrm{set}}_{k+1}$ *formula and* $\psi(x)$ *is any* $\Pi^{\mathrm{set}}_{k+1}$ *formula in which* $v$ *does not occur freely.*

Proof. This follows easily from the intertranslatability of $\Sigma^1_{k+2}$ with $\Sigma^{\mathrm{set}}_{k+1}$ (theorem VII.3.24) together with the equivalence of $\mathsf{ATR}_0$ with $|\mathsf{ATR}_0^{\mathrm{set}}|$ (theorem VII.3.22). □

We shall now show that each of $\Pi^1_{k+1}\text{-}\mathsf{CA}_0$ and $\Delta^1_{k+2}\text{-}\mathsf{CA}_0$, $0 \leq k < \omega$ implies its own relativization to the inner model $\mathrm{HCL}(X)$ (definition VII.4.22).

THEOREM VII.5.4. *In* $\mathsf{ATR}_0^{\mathrm{set}}$, *assume* $0 \leq k < \omega$ *and let* $X \subseteq \omega$ *be given. Then*:

1. $\Pi^1_{k+1}$-$\mathsf{CA}_0$ *implies* $(\Pi^1_{k+1}\text{-}\mathsf{CA}_0)^{\mathrm{HCL}(X)}$.
2. $\Delta^1_{k+2}$-$\mathsf{CA}_0$ *implies* $(\Delta^1_{k+2}\text{-}\mathsf{CA}_0)^{\mathrm{HCL}(X)}$.

PROOF. In the case when $\mathrm{HCL}(X)$ is not all of $\mathrm{L}(X)$, the desired result follows by theorem VII.4.34 (in fact we get the much stronger conclusion $(\Pi^1_\infty\text{-}\mathsf{CA}_0)^{\mathrm{HCL}(X)}$). So for the rest of this proof assume that $\mathrm{HCL}(X) = \mathrm{L}(X)$.

We shall prove part 2 first. By lemma VII.5.3.2 it will suffice to prove that $\Delta^{\mathrm{set}}_{k+1}$ comprehension implies $(\Delta^{\mathrm{set}}_{k+1}$ comprehension$)^{\mathrm{HCL}(X)}$. Assume $\Delta^{\mathrm{set}}_{k+1}$ comprehension. We first claim that $\mathrm{HCL}(X)$ satisfies the scheme of $\Sigma^{\mathrm{set}}_{k+1}$ *choice*:

$$\forall x\, \exists y\, \varphi(x, y) \rightarrow \forall u\, \exists f\, \forall x\, (x \in u \rightarrow \varphi(x, f'x))$$

where $\varphi(x, y)$ is any $\Sigma^{\mathrm{set}}_{k+1}$ formula in which $f$ does not occur freely. We shall now prove this claim by induction on $k$.

Suppose first that $k = 0$. Assume that $\mathrm{HCL}(X)$ satisfies $\forall x\, \exists y\, \varphi(x, y)$ where $\varphi(x, y)$ is a $\Sigma^{\mathrm{set}}_1$ formula with parameters from $\mathrm{HCL}(X)$. Let $u \in \mathrm{HCL}(X)$ be given. Let $g \in \mathrm{HCL}(X)$ be an injection such that $\mathrm{dom}(g) = u$ and $\mathrm{rng}(g) \subseteq \omega$. Write $\varphi(x, y)$ as $\exists z\, \theta(x, y, z)$ where $\theta(x, y, z)$ is $\Sigma^{\mathrm{set}}_0$ with parameters in $\mathrm{HCL}(X)$. For each $x \in u$, let $h_x$ be the $<^{\mathrm{L}(X)}$-least injection such that $\mathrm{dom}(h_x) = \omega$ and $\mathrm{rng}(h_x)$ is an ordinal $\alpha = \alpha_x$ such that

$$u \in \mathrm{L}_\alpha(X) \wedge \exists y\, \exists z\, (y \in \mathrm{L}_\alpha(X) \wedge z \in \mathrm{L}_\alpha(X) \wedge \theta(x, y, z)).$$

Let $\prec$ be the well ordering of $u \times \omega$ such that $\langle x, m\rangle \prec \langle x_1, m_1\rangle$ if and only if either (i) $g'x < g'x_1$ or (ii) $x = x_1$ and $h'_x m < h'_x m_1$. This well ordering $\prec$ exists by $\Delta^{\mathrm{set}}_1$ comprehension using lemmas VII.4.26 and VII.4.23.2. Now by Axiom Beta let $\beta$ be the order type of $\prec$. Thus $\beta$ is an ordinal which is the sum of the ordinals $\alpha_x$, $x \in u$ in the order given by $g$. In particular $u \in \mathrm{L}_\beta(X)$ and

$$\forall x\, (x \in u \rightarrow \exists y\, \exists z\, (y \in \mathrm{L}_\beta(X) \wedge z \in \mathrm{L}_\beta(X) \wedge \theta(x, y, z))).$$

Let $f \in \mathrm{L}_{\beta+1}(X)$ be the set of $\langle y, x\rangle$ such that $x \in u$ and $y$ is $<^{\mathrm{L}(X)}_\beta$-least such that $\exists z\, (z \in \mathrm{L}_\beta(X) \wedge \theta(x, y, z))$. Thus $f \in \mathrm{L}(X) = \mathrm{HCL}(X)$ and $\mathrm{HCL}(X)$ satisfies $\forall x\, (x \in u \rightarrow \varphi(x, f'x))$. This proves our claim for $k = 0$.

Next suppose that $k > 0$. By the inductive hypothesis, $\mathrm{HCL}(X)$ satisfies $\Sigma^{\mathrm{set}}_k$ choice. This implies that, for any $\Sigma^{\mathrm{set}}_k$ formula $\theta$, $\mathrm{HCL}(X)$ satisfies the equivalence of $\forall x\, (x \in u \rightarrow \exists y \theta)$ with $\exists v\, \forall x\, (x \in u \rightarrow \exists y\, (y \in v \wedge \theta))$. By repeated application of this quantifier interchange principle, we see that for any $\Sigma^{\mathrm{set}}_k$ formula $\theta$, $\mathrm{HCL}(X)$ satisfies the equivalence of $\forall x\, (x \in u \rightarrow \theta)$ with a certain $\Sigma^{\mathrm{set}}_k$ formula. In other words, over $\mathrm{HCL}(X)$, the class of

$\Sigma^{\rm set}_k$ formulas is closed under bounded quantification. Keep in mind also that by lemma VII.4.23, for any $\Sigma^{\rm set}_k$ formula $\theta$, the relativization $\theta^{{\rm HCL}(X)}$ is also $\Sigma^{\rm set}_k$.

Assume now that ${\rm HCL}(X)$ satisfies $\forall x\,\exists y\,\varphi(x,y)$ where $\varphi(x,y)$ is $\Sigma^{\rm set}_{k+1}$ with parameters in ${\rm HCL}(X)$. Let $u \in {\rm HCL}(X)$ be given. Let $g$ be as before. Write $\varphi(x,y)$ as $\exists z\,\theta(x,y,z)$ where $\theta(x,y,z)$ is $\Pi^{\rm set}_k$. For each $x \in u$, let $h_x$ be the $<^{{\rm L}(X)}$-least injection such that ${\rm dom}(h_x) = \omega$ and ${\rm rng}(h_x)$ is an ordinal $\alpha = \alpha_x$ such that ${\rm HCL}(X)$ satisfies $\exists y\,\exists z\,(y \in {\rm L}_\alpha(X) \wedge z \in {\rm L}_\alpha(X) \wedge \theta(x,y,z))$. Define $\prec$ as before. This well ordering $\prec$ exists by $\Delta^{\rm set}_{k+1}$ comprehension using lemma VII.4.26 and the above observations concerning bounded quantifiers. Define $\beta$ as before. Let $f$ be the set of all $\langle y,x\rangle$ such that $x \in u$ and $y$ is $<^{{\rm L}(X)}_\beta$-least such that ${\rm HCL}(X)$ satisfies $\exists z\,(z \in {\rm L}_\beta(X) \wedge \theta(x,y,z))$. By our observations on bounded quantifiers, this definition of $f$ is $\Delta^{\rm set}_k$. By induction on $k$, ${\rm HCL}(X)$ satisfies $\Delta^{\rm set}_k$ comprehension. Hence $f \in {\rm HCL}(X)$, and clearly ${\rm HCL}(X)$ satisfies $\forall x\,(x \in u \to \varphi(x, f'x))$. This proves our claim.

To complete the proof of part 2, assume that ${\rm HCL}(X)$ satisfies $\forall x\,(\varphi(x) \leftrightarrow \psi(x))$ where $\varphi(x)$ and $\psi(x)$ are $\Sigma^{\rm set}_{k+1}$, respectively $\Pi^{\rm set}_{k+1}$ formulas with parameters in ${\rm HCL}(X)$. Let $\eta(x,y)$ be the $\Sigma^{\rm set}_{k+1}$ formula

$$(y = 1 \wedge \varphi(x)) \vee (y = 0 \wedge \neg\psi(x)).$$

Then ${\rm HCL}(X)$ satisfies $\forall x\,\exists y\,\eta(x,y)$. Given $u \in {\rm HCL}(X)$, apply $\Sigma^{\rm set}_{k+1}$ choice in ${\rm HCL}(X)$ to obtain $f \in {\rm HCL}(X)$ such that ${\rm HCL}(X)$ satisfies $\forall x\,(x \in u \to \eta(x, f'x))$. Putting $v = \{x\colon x \in u \wedge f'x = 1\}$, we see that $v \in {\rm HCL}(X)$ and ${\rm HCL}(X)$ satisfies $\forall x\,(x \in v \leftrightarrow (x \in u \wedge \psi(x))$. Thus ${\rm HCL}(X)$ satisfies $\Delta^{\rm set}_{k+1}$ comprehension. This completes the proof of part 2.

We shall now prove part 1. By lemma VII.5.3.1 it will suffice to prove that $\Pi^{\rm set}_{k+1}$ comprehension implies $(\Pi^{\rm set}_{k+1}\ \text{comprehension})^{{\rm HCL}(X)}$. Assume $\Pi^{\rm set}_{k+1}$ comprehension. Let $\psi(x)$ be a $\Pi^{\rm set}_{k+1}$ formula with parameters in ${\rm HCL}(X)$ and no free variables other than $x$. Let $u \in {\rm HCL}(X)$ be given. By lemma VII.4.23 and $\Pi^{\rm set}_{k+1}$ comprehension, let $v$ be the set of $x \in u$ such that ${\rm HCL}(X)$ satisfies $\psi(x)$. Write $\psi(x)$ as $\forall y\,\theta(x,y)$ where $\theta(x,y)$ is $\Sigma^{\rm set}_k$. As before, let $\beta$ be a sum of ordinals $\alpha_x$, $x \in u - v$, where $\alpha = \alpha_x$ is chosen so that $\exists y\,(y \in {\rm L}_\alpha(X) \wedge \neg\theta(x,y))$. Thus $v$ may be described as the set of $x \in u$ such that ${\rm HCL}(X)$ satisfies $\forall y\,(y \in {\rm L}_\beta(X) \to \theta(x,y))$. By our observations concerning bounded quantifiers, the latter formula is equivalent over ${\rm HCL}(X)$ to a $\Sigma^{\rm set}_k$ formula with parameters in ${\rm HCL}(X)$. Applying $\Sigma^{\rm set}_k$ comprehension within ${\rm HCL}(X)$, it follows that $v \in {\rm HCL}(X)$.

This completes the proof of theorem VII.5.4. □

Exercise VII.5.5. In $\mathsf{ATR}^{\rm set}_0$, show that for all $X \subseteq \omega$, ${\rm L}(X)$ and ${\rm HCL}(X)$ satisfy $\Sigma^{\rm set}_1$ choice.

EXERCISE VII.5.6. Show that $\Delta^{\text{set}}_1$ comprehension is equivalent over $\mathsf{ATR}^{\text{set}}_0$ to $\Sigma^{\text{set}}_1$ choice.

EXERCISE VII.5.7. Show that $\Delta^{\text{set}}_1$ comprehension fails in the minimum transitive model of $\Pi^1_1$-$\mathsf{CA}^{\text{set}}_0$. (By lemma VII.5.3 we may restate this as follows: $\Delta^1_2$-$\mathsf{CA}_0$ fails in the minimum $\beta$-model of $\Pi^1_1$-$\mathsf{CA}_0$.)

We shall now reformulate the previous theorem so as to apply directly to subsystems of $\mathsf{Z}_2$ and models of same. Some of our results will be stated as *conservation theorems* (see definition VII.5.12 below).

DEFINITION VII.5.8. In the language $\mathrm{L}_2$, we write $Y \in \mathrm{L}(X)$ and $Z <^{\mathrm{L}(X)} Y$ as abbreviations for

$$\exists V_0 \exists V_1 (V_0 = X^* \wedge V_1 = Y^* \wedge |v_1 \in \mathrm{L}(v_0)|)$$

and

$$\exists V_0 \exists V_1 \exists V_2 (V_0 = X^* \wedge V_1 = Y^* \wedge V_2 = Z^* \wedge |v_2 <^{\mathrm{L}(v_0)} v_1|)$$

respectively. By lemma VII.4.21 and theorem VII.3.24.1, the above formulas are $\Sigma^1_2$, provably in $\mathsf{ATR}_0$.

REMARK VII.5.9. The point of the above definition is as follows. Let $M$ be a model of $\mathsf{ATR}_0$. Given $X, Y \in \mathcal{S}_M$, identify $X$ and $Y$ with the corresponding elements $[X^*]$ and $[Y^*]$ of $|M_{\text{set}}|$ (definitions VII.3.18 and VII.3.28). Then $M \models Y \in \mathrm{L}(X)$ if and only if $M_{\text{set}} \models Y \in \mathrm{L}(X)$. A similar remark applies to the formula $Z <^{\mathrm{L}(X)} Y$.

THEOREM VII.5.10. *Let $M'$ be any model of $\Pi^1_1$-$\mathsf{CA}_0$. Given $X \in \mathcal{S}_{M'}$, let $M$ be the $\omega$-submodel of $M'$ consisting of all $Y \in \mathcal{S}_{M'}$ such that $M' \models Y \in \mathrm{L}(X)$. Then*:

1. *$M$ is a model of $\Pi^1_1$-$\mathsf{CA}_0$.*
2. *$X \in \mathcal{S}_M$, and $M$ satisfies $\forall Y\, (Y \in \mathrm{L}(X))$.*
3. *$M$ is a $\beta_2$-submodel of $M'$. This means that for any $\Sigma^1_2$ sentence $\varphi$ with parameters from $M$, $M \models \varphi$ if and only if $M' \models \varphi$.*
4. *If $M'$ is a $\beta$-model, then so is $M$.*
5. *If $M'$ is an $\omega$-model, then so is $M$.*

*Furthermore, for all $k \geq 0$, we have*:

6. *To any $\Sigma^1_{k+2}$ formula $\varphi(n_1, \ldots, n_i, X_1, \ldots, X_j)$ with parameters from $M$, we can associate a $\Sigma^1_{k+2}$ formula $\varphi'$ such that, for all $n_1, \ldots, n_i \in |M|$ and $X_1, \ldots, X_j \in \mathcal{S}_M$,*

$$M \models \varphi(n_1, \ldots, n_i, X_1, \ldots, X_j)$$

*if and only if*

$$M' \models \varphi'(n_1, \ldots, n_i, X_1, \ldots, X_j).$$

7. *If $M'$ is model of $\Delta^1_{k+2}$-$\mathsf{CA}_0$, then so is $M$.*

8. *If $M'$ is a model of $\Pi^1_{k+2}$-$\mathsf{CA}_0$, then so is $M$.*
9. *If $M'$ is a model of $\Pi^1_\infty$-$\mathsf{CA}_0$, then so is $M$.*

PROOF. Clearly $M_{\text{set}}$ is the transitive submodel of $M'_{\text{set}}$ consisting of all $a \in |M'_{\text{set}}|$ such that $M'_{\text{set}} \models a \in \mathrm{HCL}(X)$. It follows by theorem VII.4.27.1 that $M_{\text{set}}$ satisfies $\mathrm{V} = \mathrm{HCL}(X)$ plus all axioms of $\Pi^1_1$-$\mathsf{CA}^{\text{set}}_0$. Hence $M$ satisfies $\forall Y\,(Y \in \mathrm{L}(X))$ plus $\Pi^1_1$-$\mathsf{CA}_0$. This gives parts 1 and 2 of the theorem. Part 3 follows from theorem VII.4.14. Part 4 follows immediately from part 3. Part 5 is trivial. For part 6, let $\varphi(n_1, \dots, n_i, X_1, \dots, X_j)$ be a given $\Sigma^1_{k+2}$ formula. By theorem VII.3.24.2, we may regard $\varphi$ as a $\Sigma^{\text{set}}_{k+1}$ formula of $\mathrm{L}_{\text{set}}$. Hence by lemma VII.4.23.2, $\varphi^{\mathrm{HCL}(X)}$ is $\Sigma^{\text{set}}_{k+1}$. Let $\varphi'(n_1, \dots, n_i, X_1, \dots, X_j)$ be the $\mathrm{L}_2$-formula

$$\exists V_1 \cdots \exists V_i\, \exists V_{i+1} \cdots \exists V_{i+j}$$
$$(V_1 = n_1^* \wedge \cdots \wedge V_i = n_i^* \wedge V_{i+1} = X_1^* \wedge \cdots \wedge V_{i+j} = X_j^*$$
$$\wedge\, |\varphi^{\mathrm{HCL}(X)}(v_1, \dots, v_i, v_{i+1}, \dots, v_{i+j})|).$$

By theorem VII.3.24.1, $\varphi'$ is $\Sigma^1_{k+2}$, and clearly $\varphi'$ satisfies the conclusion of part 6. Parts 7 and 8 follow from theorems VII.5.4.2 and VII.5.4.1 respectively. Part 9 is an immediate consequence of part 8. □

From the above theorem we can deduce the following key result.

COROLLARY VII.5.11 (conservation theorems). *Let $T_0$ be any one of the $\mathrm{L}_2$-theories $\Pi^1_\infty$-$\mathsf{CA}_0$, $\Pi^1_{k+1}$-$\mathsf{CA}_0$, or $\Delta^1_{k+2}$-$\mathsf{CA}_0$, $0 \le k < \omega$. Let $\psi$ be any $\Pi^1_4$ sentence. Suppose that $\psi$ is provable from $T_0$ plus $\exists X\, \forall Y\, (Y \in \mathrm{L}(X))$. Then $\psi$ is provable from $T_0$ alone.*

PROOF. Let $\psi$ be a $\Pi^1_4$ sentence which is not provable from $T_0$. By Gödel's completeness theorem, let $M'$ be a model of $T_0$ plus $\neg\psi$. Write $\neg\psi$ as $\exists X\, \forall Y\, \varphi(X, Y)$ where $\varphi(X, Y)$ is a $\Sigma^1_2$ formula. Let $X \in \mathcal{S}_{M'}$ be such that $M' \models \forall Y\, \varphi(X, Y)$. Let $M \subseteq_\omega M'$ consist of all $Y \in \mathcal{S}_{M'}$ such that $M' \models Y \in \mathrm{L}(X)$. By theorem VII.5.10, $M$ satisfies $T_0$ plus $\forall Y\,(Y \in \mathrm{L}(X))$ plus $\forall Y\, \varphi(X, Y)$. Thus $M$ is a model of $T_0$ plus $\exists X\, \forall Y\, (Y \in \mathrm{L}(X))$ plus $\neg\psi$. Therefore, by the soundness theorem, $\psi$ is not provable from $T_0$ plus $\exists X\, \forall Y\, (Y \in \mathrm{L}(X))$. This proves the corollary. □

The content of the above corollary is that, when trying to prove a $\Pi^1_4$ sentence within $T_0$, it is harmless to assume $\exists X\, \forall Y\, (Y \in \mathrm{L}(X))$. In other words, using the terminology of the following definition, $T_0$ plus $\exists X\, \forall Y\, (Y \in \mathrm{L}(X))$ is conservative over $T_0$ for $\Pi^1_4$ sentences. Results of this kind are sometimes known as *conservation theorems*. Other conservation theorems will be presented in the next section and in chapter IX.

DEFINITION VII.5.12 (conservativity). Let $T_0$ and $T'_0$ be theories in the language $\mathrm{L}_2$. We say that $T'_0$ is *conservative over $T_0$ for $\Pi^1_k$* sentences if

$T_0' \supseteq T_0$ and any $\Pi^1_k$ sentence which is provable in $T_0'$ is already provable in $T_0$.

EXERCISE VII.5.13 (more conservation theorems). Assume $0 \leq k \leq m \leq n \leq \infty$. Let $T_0$ consist of either $\Pi^1_{k+1}$-$\mathsf{CA}_0$ or $\Delta^1_{k+2}$-$\mathsf{CA}_0$, plus $\Pi^1_{m+1}$-$\mathsf{TI}_0$ plus $\Sigma^1_{n+1}$-$\mathsf{IND}$ (definitions VII.5.1, VII.2.14, and VII.6.1.2). Show that $T_0$ plus $\exists X \forall Y (Y \in \mathrm{L}(X))$ is conservative over $T_0$ for $\Pi^1_4$ sentences.

EXERCISE VII.5.14 ($\omega$-model conservation theorems). Assume $0 \leq k \leq m \leq \infty$. Let $T_0$ consist of either $\Pi^1_{k+1}$-$\mathsf{CA}_0$ or $\Delta^1_{k+2}$-$\mathsf{CA}_0$, plus $\Pi^1_{m+1}$-$\mathsf{TI}_0$. Let $\psi$ be any $\Pi^1_4$ sentence. Suppose that $\psi$ holds in all $\omega$-models of $T_0$ plus $\exists X \forall Y (Y \in \mathrm{L}(X))$. Show that $\psi$ holds in all $\omega$-models of $T_0$.

EXERCISE VII.5.15 ($\beta$-model conservation theorems). Let $T_0$ and $\psi$ be as in corollary VII.5.11. Suppose that $\psi$ holds in all transitive models of $T_0$ of the form $\mathrm{L}_\alpha(X)$, $X \subseteq \omega$, $\alpha$ a countable ordinal. Show that $\psi$ holds in all $\beta$-models of $T_0$.

EXERCISE VII.5.16. Show that the results of corollary VII.5.11 and exercises VII.5.13, VII.5.14 and VII.5.15 do not extend to $\Sigma^1_4$ sentences.

Hint: The sentence $\exists X \forall Y (Y \in \mathrm{L}(X))$ is $\Sigma^1_4$. Consider a transitive model of ZFC in which the continuum hypothesis does not hold.

We shall now apply theorem VII.5.10 to obtain the minimum $\beta$-models of $\Pi^1_{k+1}$-$\mathsf{CA}_0$ and $\Delta^1_{k+2}$-$\mathsf{CA}_0$, $0 \leq k < \omega$, and of $\Pi^1_\infty$-$\mathsf{CA}_0$.

THEOREM VII.5.17 (minimum $\beta$-models). *Assume $X \subseteq \omega$ and $0 \leq k < \omega$.*

1. *Among all $\beta$-models of $\Pi^1_{k+1}$-$\mathsf{CA}_0$ which contain $X$, there is a unique smallest one $M = \mathrm{M}^\Pi_{k+1}(X)$. Furthermore $M_{\mathrm{set}}$ can be characterized (up to canonical isomorphism) as $\mathrm{L}_\alpha(X)$ for a certain ordinal $\alpha = \alpha^\Pi_{k+1}(X)$, namely the smallest ordinal $\alpha$ such that $\mathrm{L}_\alpha(X)$ satisfies $\Pi^1_{k+1}$ comprehension.*
2. *Same as part 1 with $\Pi^1_{k+1}$, $\mathrm{M}^\Pi_{k+1}(X)$, $\alpha^\Pi_{k+1}(X)$ replaced by $\Delta^1_{k+2}$, $\mathrm{M}^\Delta_{k+2}(X)$, $\alpha^\Delta_{k+2}(X)$ respectively.*
3. *Same as part 1 with $\Pi^1_{k+1}$, $\mathrm{M}^\Pi_{k+1}(X)$, $\alpha^\Pi_{k+1}(X)$ replaced by $\Pi^1_\infty$, $\mathrm{M}^\Pi_\infty(X)$, $\alpha^\Pi_\infty(X)$ respectively.*

PROOF. Let $M'$ be any $\beta$-model of $\Pi^1_{k+1}$-$\mathsf{CA}_0$ which contains $X$. Let $M \subseteq_\omega M'$ consist of all $Y \in M'$ such that $M' \models Y \in \mathrm{L}(X)$. By theorem VII.5.10, $M$ is a $\beta$-model of $\Pi^1_{k+1}$-$\mathsf{CA}_0$ and $M$ satisfies $\forall Y (Y \in \mathrm{L}(X))$. Thus $M_{\mathrm{set}}$ is isomorphic to a transitive model of $\Pi^1_{k+1}$-$\mathsf{CA}^{\mathrm{set}}_0$ plus $\mathrm{V} = \mathrm{HCL}(X)$. By lemma VII.4.21, this model is $\mathrm{L}_\beta(X)$ for some ordinal $\beta$. Then clearly $\beta \geq \alpha$ where $\alpha = \alpha^\Pi_{k+1}(X)$ is as defined in the statement of part 1. Put $\mathrm{M}^\Pi_{k+1}(X) = (\mathrm{L}_\alpha(X))^2$. Then $\mathrm{M}^\Pi_{k+1}(X)$ satisfies $\Pi^1_{k+1}$-$\mathsf{CA}_0$ by definition, and is a $\beta$-model by theorem VII.3.27.2. Also

$\mathrm{M}^{\Pi}_{k+1}(X) \subseteq M \subseteq M'$ so part 1 is proved. The proofs of parts 2 and 3 are similar. □

Remark VII.5.18. In §VII.7 we shall see that for all $X \subseteq \omega$ and $0 \leq k < \omega$,

$$\alpha^{\Pi}_{k+1}(X) < \alpha^{\Delta}_{k+2}(X) < \alpha^{\Pi}_{k+2}(X).$$

In §§VIII.3 and VIII.4 we shall obtain an analogous ordinal $\alpha^{\Delta}_1(X) < \alpha^{\Pi}_1(X)$. Namely, setting $\alpha = \alpha^{\Delta}_1(X) = \sup\{|a|^X : \mathcal{O}(a, X)\}$ and $M = \mathrm{M}^{\Delta}_1(X) = \mathrm{HYP}(X)$, we shall see that $M = \mathrm{L}_\alpha(X) \cap P(\omega)$ is the minimum $\omega$-model of $\Delta^1_1$-$\mathsf{CA}_0$.

Exercise VII.5.19 (minimum $\beta$-submodels). Assume $0 \leq k < \omega$ and let $X \in M' \models \Pi^1_{k+1}$-$\mathsf{CA}_0$ be given. Prove that among all $\beta$-submodels $M \subseteq_\beta M'$ such that $X \in M \models \Pi^1_{k+1}$-$\mathsf{CA}_0$, there is a unique smallest one. Describe this model. Prove similar results with $\Pi^1_{k+1}$-$\mathsf{CA}_0$ replaced by $\Delta^1_{k+2}$-$\mathsf{CA}_0$ and by $\Pi^1_\infty$-$\mathsf{CA}_0$.

Exercise VII.5.20. Recall the system $\Pi^1_k$-$\mathsf{TR}_0$, definition VI.7.1. Extend VII.5.10–VII.5.19 to encompass $\Pi^1_{k+1}$-$\mathsf{TR}_0$, $0 \leq k < \omega$. In particular we have a result similar to VII.5.17.1 with $\Pi^1_{k+1}$-$\mathsf{CA}_0$, $\mathrm{M}^{\Pi}_{k+1}(X)$, $\alpha^{\Pi}_{k+1}(X)$, $\Pi^1_{k+1}$ comprehension replaced by $\Pi^1_{k+1}$-$\mathsf{TR}_0$, $\mathrm{M}^{\Pi^*}_{k+1}(X)$, $\alpha^{\Pi^*}_{k+1}(X)$, $\Pi^1_{k+1}$ transfinite recursion respectively. Thus we obtain minimum $\beta$-models of $\Pi^1_{k+1}$-$\mathsf{TR}_0$, $0 \leq k < \omega$. (See also exercises VII.7.12.)

**Notes for §VII.5.** The ideas of this section are probably well known, but we have been unable to find bibliographical references for them. Our sharp formulations VII.5.10–VII.5.16 in terms of conservation results are probably new.

Our results on minimum $\beta$-models of $\Delta^1_k$-$\mathsf{CA}_0$ and $\Pi^1_k$-$\mathsf{CA}_0$ are closely related to some well known ideas of Barwise and Jensen. In order to explain this connection, let us use the notation of VII.5.17 and VII.5.18 and write $\alpha^{\Delta}_k = \alpha^{\Delta}_k(\emptyset)$ and $\alpha^{\Pi}_k = \alpha^{\Pi}_k(\emptyset)$, where $\emptyset$ is the empty set. For $k = 1$, the ordinals $\alpha^{\Delta}_1$ and $\alpha^{\Pi}_1$ can be characterized in terms of admissibility theory, as discussed in Barwise [13], Simpson [233], and Sacks [211]. Namely, $\alpha^{\Delta}_1 = \omega_1^{\mathrm{CK}}$ = the least admissible ordinal $> \omega$, and $\alpha^{\Pi}_1$ = the supremum of the first $\omega$ admissible ordinals. (Note however that $\alpha^{\Pi}_1$ is not itself admissible.) Moreover, for arbitrary $k < \omega$, the ordinals $\alpha^{\Delta}_{k+2}$ and $\alpha^{\Pi}_{k+2}$ can be characterized in terms of Jensen's fine structure theory [131]; see also Simpson [233, §3]. Namely, $\alpha^{\Delta}_{k+2}$ = the least $\alpha$ such that $\eta^{\alpha}_{k+1} > \omega$, or equivalently the least $\alpha > \omega$ such that $\eta^{\alpha}_{k+1} = \alpha$; and $\alpha^{\Pi}_{k+2}$ = the least $\alpha$ such that $\rho^{\alpha}_{k+1} > \omega$, or equivalently the least $\alpha > \omega$ such that $\rho^{\alpha}_{k+1} = \alpha$. These results are easily deduced from theorems VII.3.24 and VII.5.17.

## VII.6. Strong Choice Schemes

The purpose of this section is to study the axiom of choice in the context of second order arithmetic. We shall consider several *choice schemes*, i.e., axiom schemes in the language $L_2$ which express consequences or special cases of the axiom of choice. We shall obtain some conservation theorems relating strong choice schemes to strong comprehension schemes. We make essential use of the results of the previous two sections.

DEFINITION VII.6.1 (choice schemes). Assume $0 \leq k < \omega$.

1. $\Sigma^1_k$-$\mathsf{AC}_0$ is the $L_2$-theory whose axioms are those of $\mathsf{ACA}_0$ plus the scheme of $\Sigma^1_k$ *choice*:
$$\forall n\, \exists Y\, \eta(n, Y) \to \exists Z\, \forall n\, \eta(n, (Z)_n)$$
where $\eta(n, Y)$ is any $\Sigma^1_k$ formula in which $Z$ does not occur. We are using the notation
$$(Z)_n = \{i : (i, n) \in Z\}.$$
2. $\Sigma^1_k$-$\mathsf{IND}$ is the scheme of $\Sigma^1_k$ *induction*:
$$(\varphi(0) \wedge \forall n\, (\varphi(n) \to \varphi(n+1))) \to \forall n\, \varphi(n)$$
where $\varphi(n)$ is any $\Sigma^1_k$ formula. We also define $\Sigma^1_\infty$-$\mathsf{IND} = \bigcup_{k<\omega} \Sigma^1_k$-$\mathsf{IND}$. Note that $\Sigma^1_\infty$-$\mathsf{IND}$ automatically holds in all $\omega$-models.
3. $\Sigma^1_k$-$\mathsf{DC}_0$ is the $L_2$-theory whose axioms are those of $\mathsf{ACA}_0$ plus the scheme of $\Sigma^1_k$ *dependent choice*:
$$\forall n\, \forall X\, \exists Y\, \eta(n, X, Y) \to \exists Z\, \forall n\, \eta(n, (Z)^n, (Z)_n)$$
where $\eta(n, X, Y)$ is any $\Sigma^1_k$ formula in which $Z$ does not occur. We are using the notation
$$(Z)^n = \{(i, m) : (i, m) \in Z \wedge m < n\}$$
and $(Z)_n$ as above.
4. *Strong* $\Sigma^1_k$-$\mathsf{DC}_0$ is the $L_2$-theory whose axioms are those of $\mathsf{ACA}_0$ plus the scheme of *strong* $\Sigma^1_k$ *dependent choice*:
$$\exists Z\, \forall n\, \forall Y\, (\eta(n, (Z)^n, Y) \to \eta(n, (Z)^n, (Z)_n))$$
where $\eta(n, X, Y)$ is as above.

We begin with a number of miscellaneous remarks concerning $\Sigma^1_k$-$\mathsf{AC}_0$, $\Sigma^1_k$-$\mathsf{DC}_0$, and strong $\Sigma^1_k$-$\mathsf{DC}_0$, $0 \leq k < \omega$.

REMARKS VII.6.2. Trivially $\Sigma^1_0$-$\mathsf{AC}_0$ is equivalent to $\Sigma^1_1$-$\mathsf{AC}_0$ and $\Sigma^1_0$-$\mathsf{DC}_0$ is equivalent to $\Sigma^1_1$-$\mathsf{DC}_0$. It is easy to see that
$$\Delta^1_1\text{-}\mathsf{CA}_0 \subseteq \Sigma^1_1\text{-}\mathsf{AC}_0 \subseteq \Sigma^1_1\text{-}\mathsf{DC}_0$$
(lemma VII.6.6) and that $\Sigma^1_1$-$\mathsf{DC}_0$ holds in all $\beta$-models of $\mathsf{ATR}_0$. Also, by theorem V.8.3, $\Sigma^1_1$-$\mathsf{AC}_0$ holds in all models of $\mathsf{ATR}_0$. Further results

concerning $\Delta^1_1$-$\mathsf{CA}_0$, $\Sigma^1_1$-$\mathsf{AC}_0$ and $\Sigma^1_1$-$\mathsf{DC}_0$ will be presented in chapters VIII and IX.

Remarks VII.6.3 ($\Sigma^1_k$-$\mathsf{AC}_0$). The cases $k = 0$ and $k = 1$ are discussed in remark VII.6.2 and in chapters VIII and IX. It is easy to see that $\Sigma^1_k$-$\mathsf{AC}_0$ implies $\Delta^1_k$-$\mathsf{CA}_0$ (lemma VII.6.6.1). For $k = 2$, we shall see below (theorem VII.6.9.1) that $\Sigma^1_2$-$\mathsf{AC}_0$ is in fact equivalent to $\Delta^1_2$-$\mathsf{CA}_0$. For $k \geq 3$ the situation is more complex. On the one hand, Feferman and Lévy have used forcing to exhibit a $\beta$-model $M$ of $\Pi^1_\infty$-$\mathsf{CA}_0$ in which $\Sigma^1_3$-$\mathsf{AC}_0$ fails. Namely, $M = A \cap P(\omega)$ where $A$ is a transitive model of ZF plus $\aleph_1 = \aleph^{\mathrm{L}}_\omega$. See Lévy [163, theorem 8], Cohen [40, §IV.10], and Jech [130, §21, example IV]. On the other hand, we shall see below (theorem VII.6.16.1) that for all $k$, $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ is equivalent to $\Delta^1_{k+3}$-$\mathsf{CA}_0$ if we assume $\exists X \, \forall Y \, (Y \in \mathrm{L}(X))$. See also remarks VII.6.12 and VII.6.21 below.

Remarks VII.6.4 ($\Sigma^1_k$-$\mathsf{DC}_0$). The cases $k = 0$ and $k = 1$ are discussed in remark VII.6.2 and in chapters VIII and IX. It is easy to see that $\Sigma^1_k$-$\mathsf{DC}_0$ implies $\Sigma^1_k$-$\mathsf{AC}_0$ plus $\Sigma^1_k$-IND (lemma VII.6.6.2). For $k = 2$, we shall see below (theorem VII.6.9.2) that $\Sigma^1_2$-$\mathsf{DC}_0$ is in fact equivalent to $\Sigma^1_2$-$\mathsf{AC}_0$ plus $\Sigma^1_2$-IND. Simpson [229] has claimed that there exists a $\beta$-model of $\Sigma^1_\infty$-$\mathsf{AC}_0$ ( $= \bigcup_{k<\omega} \Sigma^1_k$-$\mathsf{AC}_0$) in which $\Sigma^1_3$-$\mathsf{DC}_0$ fails; the proof of this result has not been published. We shall see below (theorem VII.6.16.2) that for all $k$, $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ is equivalent to $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ plus $\Sigma^1_{k+3}$-IND if we assume $\exists X \, \forall Y \, (Y \in \mathrm{L}(X))$.

In some of these results, the role of $\Sigma^1_k$-IND is rather delicate. See remarks VII.6.12 and VII.6.21 below. Of course we may ignore this delicate issue if we are interested only in $\omega$-models, since in all such models $\Sigma^1_\infty$-IND automatically holds.

Remarks VII.6.5 (strong $\Sigma^1_k$-$\mathsf{DC}_0$). Trivially strong $\Sigma^1_0$-$\mathsf{DC}_0$ is equivalent to strong $\Sigma^1_1$-$\mathsf{DC}_0$. It is easy to see (lemma VII.6.6.3) that strong $\Sigma^1_k$-$\mathsf{DC}_0$ implies $\Pi^1_k$-$\mathsf{CA}_0$. We shall see below (theorem VII.6.9) that strong $\Sigma^1_1$-$\mathsf{DC}_0$ is in fact equivalent to $\Pi^1_1$-$\mathsf{CA}_0$. Likewise, strong $\Sigma^1_2$-$\mathsf{DC}_0$ is equivalent to $\Pi^1_2$-$\mathsf{CA}_0$. Furthermore (theorem VII.6.16.3), for all $k$, strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ is equivalent to $\Pi^1_{k+3}$-$\mathsf{CA}_0$ if we assume $\exists X \, \forall Y \, (Y \in \mathrm{L}(X))$. We do not know whether strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ is equivalent to $\Pi^1_{k+3}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+3}$-$\mathsf{DC}_0$.

Lemma VII.6.6. *Assume* $0 \leq k < \omega$.

1. $\Sigma^1_k$-$\mathsf{AC}_0$ *implies* $\Delta^1_k$-$\mathsf{CA}_0$.
2. $\Sigma^1_k$-$\mathsf{DC}_0$ *implies* $\Sigma^1_k$-$\mathsf{AC}_0$ *and* $\Sigma^1_k$-IND.
3. *Strong* $\Sigma^1_k$-$\mathsf{DC}_0$ *implies* $\Pi^1_k$-$\mathsf{CA}_0$ *and* $\Sigma^1_k$-$\mathsf{DC}_0$.

Proof. For part 1, assume $\Sigma^1_k$-$\mathsf{AC}_0$ and suppose $\forall n \, (\varphi(n) \leftrightarrow \psi(n))$ where $\varphi(n)$ and $\psi(n)$ are $\Sigma^1_k$ and $\Pi^1_k$ respectively. Let $\eta(n, Y)$ be the $\Sigma^1_k$

formula

$$(\varphi(n) \wedge 1 \in Y) \vee (\neg\psi(n) \wedge 1 \notin Y).$$

By $\Sigma^1_k$ choice let $Z$ be such that $\forall n\, \eta(n, (Z)_n)$. Putting $X = \{n\colon 1 \in (Z)_n\}$ we see that $\forall n\, (n \in X \leftrightarrow \psi(n))$. This proves $\Delta^1_k$ comprehension.

For part 2, assume $\Sigma^1_k$-DC$_0$ and suppose $\forall n\, \exists Y\, \eta(n, Y)$ where $\eta(n, Y)$ is $\Sigma^1_k$. Let $\varphi(n, X, Y)$ be the $\Sigma^1_k$ formula $\eta(n, Y)$. Applying $\Sigma^1_k$ dependent choice, we get $Z$ such that $\forall n\, \varphi(n, (Z)^n, (Z)_n)$, i.e., $\forall n\, \eta(n, (Z)_n)$. This proves $\Sigma^1_k$ choice. Now to prove $\Sigma^1_k$-IND, let $\varphi(n)$ be $\Sigma^1_k$ and assume $\varphi(0)$ and $\forall n\, (\varphi(n) \rightarrow \varphi(n+1))$. Without loss we may assume $k \geq 1$ and write $\varphi(n)$ as $\exists X\, \theta(n, X)$ where $\theta(n, X)$ is $\Pi^1_{k-1}$. Let $\eta(n, X, Y)$ be the $\Sigma^1_k$ formula

$$\forall m\, (m < n \rightarrow \theta(m, (X)_m)) \rightarrow \theta(n, Y).$$

Our assumptions imply that $\forall n\, \forall X\, \exists Y\, \eta(n, X, Y)$. Applying $\Sigma^1_k$ dependent choice, we get $Z$ such that $\forall n\, \eta(n, (Z)^n, (Z)_n)$. By part 1 we have $\Pi^1_{k-1}$ comprehension. Using this, let $W$ be such that $\forall n\, (n \in W \leftrightarrow \forall m\, (m < n \rightarrow \theta(m, (Z)_m)))$. We can then use quantifier-free induction to show that $W = \mathbb{N}$. This gives $\forall n\, \theta(n, (Z)_n)$, hence $\forall n \varphi(n)$. The proof of part 2 is complete.

For part 3, assume strong $\Sigma^1_k$-DC$_0$. Trivially we have $\Sigma^1_k$-DC$_0$. It remains to prove $\Pi^1_k$-CA$_0$. Instead of $\Pi^1_k$ comprehension, we shall prove $\Sigma^1_k$ comprehension, which is equivalent. Let $\varphi(n)$ be $\Sigma^1_k$. Without loss assume $k \geq 1$ and write $\varphi(n)$ as $\exists Y\, \theta(n, Y)$ where $\theta(n, Y)$ is $\Pi^1_{k-1}$. Let $\eta(n, X, Y)$ be $\theta(n, Y)$. Applying strong $\Sigma^1_k$ dependent choice to $\eta(n, X, Y)$, we get $Z$ such that $\forall n\, \forall Y\, (\theta(n, Y) \rightarrow \theta(n, (Z)_n))$. By $\Pi^1_{k-1}$ comprehension, let $X$ be such that $\forall n\, (n \in X \leftrightarrow \theta(n, (Z)_n))$. Then $\forall n\, (n \in X \leftrightarrow \varphi(n))$. This proves $\Sigma^1_k$ comprehension.

The proof of lemma VII.6.6 is complete. □

We shall now prove some deeper results concerning the relationship between $\Sigma^1_k$ choice schemes and $\Pi^1_k$ and $\Delta^1_k$ comprehension schemes.

In order to handle the case $k = 2$, we need the following lemma. This is a formal $\Pi^1_1$-CA$_0$ version of the well known $\Sigma^1_2$ uniformization principle.

LEMMA VII.6.7 ($\Sigma^1_2$ uniformization in $\Pi^1_1$-CA$_0$). *Let $\varphi(Y)$ be a $\Sigma^1_2$ formula with a distinguished free set variable $Y$. Then we can find a $\Sigma^1_2$ formula $\widehat{\varphi}(Y)$ such that $\Pi^1_1$-CA$_0$ proves*

(1) $\forall Y\, (\widehat{\varphi}(Y) \rightarrow \varphi(Y))$,
(2) $\forall Z\, (\varphi(Z) \rightarrow \exists Y\, \widehat{\varphi}(Y))$,
(3) $\forall Y\, \forall Z\, ((\widehat{\varphi}(Y) \wedge \widehat{\varphi}(Z)) \rightarrow Y = Z)$.

PROOF. We give two proofs, one based on Kondo's theorem and the other based on the Shoenfield absoluteness theorem.

For the first proof, write $\varphi(Y)$ as $\exists W\, \psi(Y \oplus W)$ where $\psi(Y)$ is $\Pi^1_1$. We are using the notation

$$Y \oplus W = \{2n : n \in Y\} \bigcup \{2n+1 : n \in W\}.$$

Applying lemma VI.2.1 (a formal version of Kondo's $\Pi^1_1$ uniformization theorem), we obtain a $\Pi^1_1$ formula $\widehat{\psi}(Y)$ such that $\Pi^1_1$-$\mathsf{CA}_0$ proves (1), (2) and (3) with $\varphi$ replaced by $\psi$. Setting $\widehat{\varphi}(Y) \equiv \exists W\, \widehat{\psi}(Y \oplus W)$ we obtain (1), (2) and (3).

In order to present the second proof we need the following sublemma, which will be used again in the proof of lemma VII.6.15. Recall that the formulas $Y \in \mathrm{L}(X)$ and $Z <^{\mathrm{L}(X)} Y$ are $\Sigma^1_2$ (definition VII.5.8).

SUBLEMMA VII.6.8. *In* $\mathsf{ATR}_0$ *the formula*

$$\forall Z\, (Z \leq^{\mathrm{L}(X)} Y \leftrightarrow \exists n\, (Z = (W)_n)) \tag{21}$$

*is equivalent to a* $\Sigma^1_2$ *formula.*

PROOF. By lemma VII.4.21, the set-theoretic formula

$$v_3 = \{v_2 : v_2 \subseteq \omega \wedge v_2 \leq^{\mathrm{L}(v_0)} v_1\}$$

is $\Sigma^{\mathrm{set}}_1$. Recall that, according to definition VII.3.18, $Y^*$ is a suitable tree which represents $Y$. Hence

$$W^{**} = \{\langle n\rangle^\frown \sigma : n \in \mathbb{N} \wedge \sigma \in (W)^*_n\}$$

is a suitable tree which represents $\{(W)_n : n \in \mathbb{N}\}$. Thus (21) is equivalent to

$$\exists V_0\, \exists V_1\, \exists V_3\, (V_0 = X^* \wedge V_1 = Y^* \wedge V_3 = W^{**} \wedge |v_3 = \{v_2 : v_2 \subseteq \omega \wedge v_2 \leq^{\mathrm{L}(v_0)} v_1\}|).$$

This is $\Sigma^1_2$ in view of theorem VII.3.24.1. The sublemma is proved. □

Now as in the hypothesis of lemma VII.6.7, let $\varphi(Y)$ be a $\Sigma^1_2$ formula. Without loss of generality, assume that the only free set variables of $\varphi(Y)$ are $Y$ and $X$. Write $\varphi(Y)$ as $\exists W\, \psi(X, Y \oplus W)$ where $\psi(X, Y)$ is $\Pi^1_1$. Let $\widehat{\psi}(X, Y)$ be the formula

$$\exists W\, (\forall Z\, (Z \leq^{\mathrm{L}(X)} Y \leftrightarrow \exists n\, (Z = (W)_n)) \wedge \forall n\, (\psi(X, (W)_n) \leftrightarrow (W)_n = Y)).$$

We reason within $\Pi^1_1$-$\mathsf{CA}_0$. By $\Sigma^1_2$ choice, the subformula

$$\forall n\, (\psi(X, (W)_n) \leftrightarrow (W)_n = Y)$$

is equivalent to a $\Sigma^1_2$ formula. Hence, by sublemma VII.6.8, $\widehat{\psi}(X, Y)$ is also equivalent to a $\Sigma^1_2$ formula. Clearly we have $\forall Y\, (\widehat{\psi}(X, Y) \rightarrow \psi(X, Y))$ and $\forall Y\, \forall Z\, ((\widehat{\psi}(X, Y) \wedge \widehat{\psi}(X, Z)) \rightarrow Y = Z)$. By theorem VII.4.14 (a formal version of Shoenfield absoluteness), we have $\forall Z\, (\psi(X, Z) \rightarrow \exists Y\, (Y \in \mathrm{L}(X) \wedge \psi(X, Y)))$, hence $\forall Z\, (\psi(X, Z) \rightarrow \exists Y\, \widehat{\psi}(X, Y))$. Setting

$\widehat{\varphi}(Y) \equiv \exists W\, \widehat{\psi}(X, Y \oplus W)$ we obtain (1), (2) and (3). This completes the second proof of lemma VII.6.7. □

We are now ready to prove the following theorem concerning $\Sigma^1_2$ choice schemes.

THEOREM VII.6.9 ($\Sigma^1_2$ choice schemes).

1. $\Sigma^1_2$-AC$_0$ *is equivalent to* $\Delta^1_2$-CA$_0$.
2. $\Sigma^1_2$-DC$_0$ *is equivalent to* $\Delta^1_2$-CA$_0$ *plus* $\Sigma^1_2$-IND.
3. *Strong* $\Sigma^1_2$-DC$_0$ *is equivalent to* $\Pi^1_2$-CA$_0$.
4. *Strong* $\Sigma^1_1$-DC$_0$ *is equivalent to* $\Pi^1_1$-CA$_0$.

PROOF. We begin with part 1. By lemma VII.6.6.1, $\Sigma^1_2$-AC$_0$ implies $\Delta^1_2$-CA$_0$. For the converse, assume $\Delta^1_2$-CA$_0$. To prove $\Sigma^1_2$ choice, suppose $\forall n\, \exists Y\, \eta(n, Y)$ where $\eta(n, Y)$ is $\Sigma^1_2$. By lemma VII.6.7, let $\widehat{\eta}(n, Y)$ be $\Sigma^1_2$ such that $\forall n\, (\exists \text{ exactly one } Y)\, \widehat{\eta}(n, Y)$ and $\forall n\, \forall Y\, (\widehat{\eta}(n, Y) \to \eta(n, Y))$. Set

$$\varphi(i, n) \equiv \exists Y\, (\widehat{\eta}(n, Y) \wedge i \in Y)$$

and

$$\psi(i, n) \equiv \forall Y\, (\widehat{\eta}(n, Y) \to i \in Y).$$

Thus $\varphi(i, n)$ is $\Sigma^1_2$, $\psi(i, n)$ is $\Pi^1_2$, and $\forall n \forall i\, (\varphi(i, n) \leftrightarrow \psi(i, n))$. By $\Delta^1_2$ comprehension, let $Z = \{(i, n) \colon \psi(i, n)\}$. Then $\forall n\, \eta(n, (Z)_n)$. This proves part 1.

Next we prove part 2. By lemma VII.6.6.2, $\Sigma^1_2$-DC$_0$ implies $\Sigma^1_2$-AC$_0$ and $\Sigma^1_2$-IND. For the converse, assume $\Sigma^1_2$-AC$_0$ plus $\Sigma^1_2$-IND. To prove $\Sigma^1_2$ dependent choice, suppose $\forall n\, \forall X\, \exists Y\, \eta(n, X, Y)$ where $\eta(n, X, Y)$ is $\Sigma^1_2$. By lemma VII.6.7 let $\widehat{\eta}(n, X, Y)$ be such that $\forall n\, \forall X\, (\exists \text{ exactly one } Y)\, \widehat{\eta}(n, X, Y)$ and

$$\forall n\, \forall X\, \forall Y\, (\widehat{\eta}(n, X, Y) \to \eta(n, X, Y)).$$

By $\Sigma^1_2$ choice, the formula

$$\overline{\eta}(n, W) \equiv \forall m\, (m \leq n \to \widehat{\eta}(m, (W)^m, (W)_m))$$

is equivalent to a $\Sigma^1_2$ formula. We can therefore use $\Sigma^1_2$ induction to prove $\forall n\, \exists W\, \overline{\eta}(n, W)$. It is also easy to see that

$$\forall n\, \forall W\, \forall Z\, ((\overline{\eta}(n, W) \wedge \overline{\eta}(n, Z)) \to (W)_n = (Z)_n).$$

Setting

$$\varphi(i, n) \equiv \exists W\, (\overline{\eta}(n, W) \wedge i \in (W)_n)$$

and

$$\psi(i, n) \equiv \forall W\, (\overline{\eta}(n, W) \to i \in (W)_n)$$

we see that $\varphi(i, n)$ is $\Sigma^1_2$, $\psi(i, n)$ is $\Pi^1_2$, and $\forall i \forall n\, (\varphi(i, n) \leftrightarrow \psi(i, n))$. By $\Delta^1_2$ comprehension, let $Z = \{(i, n) \colon \psi(i, n)\}$. Then $\forall n\, \overline{\eta}(n, Z)$, hence $\forall n\, \eta(n, (Z)^n, (Z)_n)$. This proves part 2.

We now turn to part 3. By lemma VII.6.6.3, strong $\Sigma^1_2$-DC$_0$ implies $\Pi^1_2$-CA$_0$. For the converse, assume $\Pi^1_2$-CA$_0$ and let $\eta(n, X, Y)$ be $\Sigma^1_2$. By lemma VII.6.7 let $\widehat{\eta}(n, X, Y)$ be $\Sigma^1_2$ such that

$$\forall n\, \forall X\, \forall Y\, (\widehat{\eta}(n, X, Y) \to \eta(n, X, Y)),$$
$$\forall n\, \forall X\, \forall Z\, (\eta(n, X, Z) \to \exists Y\, \widehat{\eta}(n, X, Y)),$$
$$\forall n\, \forall X\, \forall Y\, \forall Z\, ((\widehat{\eta}(n, X, Y) \wedge \widehat{\eta}(n, X, Z)) \to Y = Z).$$

By $\Sigma^1_2$ comprehension, let $S$ be the set of all $\sigma \in 2^{<\mathbb{N}}$ such that $\exists W\, \overline{\eta}(\sigma, W)$ where $\overline{\eta}(\sigma, W)$ is the $\Sigma^1_2$ formula

$$\forall m\, (\sigma(m) = 1 \to \widehat{\eta}(m, (W)^m, (W)_m)) \wedge (\sigma(m) = 0 \to (W)_m = \emptyset)).$$

Note that $\langle\rangle \in S$ and if $\sigma \in S$ then $\sigma^\frown\langle 0\rangle \in S$. Define $f : \mathbb{N} \to \{0, 1\}$ by $f(n) = 1$ if $f[n]^\frown\langle 1\rangle \in S$, $f(n) = 0$ otherwise. Then $\forall n\, \exists W\, \overline{\eta}(f[n + 1], W)$ and it is easy to see that $\forall n\, \forall W\, \forall Z\, ((\overline{\eta}(f[n + 1], W) \wedge \overline{\eta}(f[n + 1], Z)) \to (W)_n = (Z)_n)$. As before apply $\Delta^1_2$ comprehension to get $Z = \{(i, n) : \forall W\, (\overline{\eta}(f[n + 1], W) \to i \in (W)_n)\}$. Then $\forall n\, \overline{\eta}(f[n + 1], Z)$, hence $\forall n\, \forall Y\, (\eta(n, (Z)^n, Y) \to \eta(n, (Z)^n, (Z)_n))$. This proves strong $\Sigma^1_2$ dependent choice.

It remains to prove part 4. By lemma VII.6.6.3, strong $\Sigma^1_1$-DC$_0$ implies $\Pi^1_1$-CA$_0$. For the converse, assume $\Pi^1_1$-CA$_0$ and let $\eta(n, X, Y)$ be $\Sigma^1_1$. By theorem VII.2.10, let $M$ be a countable coded $\beta$-model such that $M$ contains the parameters of $\eta(n, X, Y)$. Let $Z$ be a code for $M$ according to definition VII.2.1. By arithmetical comprehension with $Z$ as a parameter, define $f : \mathbb{N} \to \mathbb{N}$ by $f(n) =$ least $j$ such that

$$M \models \eta(n, \{(i, m) : (i, f(m)) \in Z \wedge m < n\}, (Z)_j)$$

if such $j$ exists, $f(n) = 0$ otherwise. Setting $W = \{(i, n) : (i, f(n)) \in Z\}$ we see that for all $n$, $(W)^n \in M$ and $(W)_n \in M$ and

$$M \models \forall Y\, (\eta(n, (W)^n, Y) \to \eta(n, (W)^n, (W)_n)).$$

Since $M$ is a $\beta$-model, it follows that $\forall n\, \forall Y\, (\eta(n, (W)^n, Y) \to \eta(n, (W)^n, (W)_n))$ is true. This proves strong $\Sigma^1_1$ dependent choice.

The proof of theorem VII.6.9 is complete. □

Corollary VII.6.10. *$\Delta^1_2$-CA$_0$ and $\Sigma^1_2$-AC$_0$ and $\Sigma^1_2$-DC$_0$ are all pairwise equivalent in the presence of $\Sigma^1_2$-IND.*

Proof. This follows immediately from parts 1 and 2 of theorem VII.6.9. □

Corollary VII.6.11. *The $\omega$-models of $\Delta^1_2$-CA$_0$ and of $\Sigma^1_2$-AC$_0$ are the same as those of $\Sigma^1_2$-DC$_0$.*

Proof. This follows from the previous corollary, since $\Sigma^1_\infty$-IND is true in all $\omega$-models. □

REMARK VII.6.12. In chapter IX we shall prove:

1. $\Sigma^1_2$-$\mathsf{AC}_0$ is conservative over $\Pi^1_1$-$\mathsf{CA}_0$ for $\Pi^1_3$ sentences;
2. the consistency of $\Sigma^1_2$-$\mathsf{AC}_0$ is provable from $\Pi^1_1$-$\mathsf{CA}_0$ plus $\Sigma^1_2$-IND.

From this it follows that $\Sigma^1_2$-IND is not provable in $\Sigma^1_2$-$\mathsf{AC}_0$, even if we assume $\forall Y\,(Y \in \mathrm{L}(\emptyset))$. Hence the assumption $\Sigma^1_2$-IND cannot be dropped from VII.6.9.2 or VII.6.10.

EXERCISE VII.6.13 ($\Pi^1_2$ separation). Show that $\Delta^1_2$-$\mathsf{CA}_0$ is equivalent over $\mathsf{ACA}_0$ to the $\Pi^1_2$ *separation principle*:

$$\neg\exists n\,(\psi(n,1) \wedge \psi(n,0)) \rightarrow \exists X\,\forall n\,((\psi(n,1) \rightarrow n \in X) \wedge (\psi(n,0) \rightarrow n \notin X))$$

where $\psi(n,i)$ is any $\Pi^1_2$ formula in which $X$ does not occur freely.

EXERCISE VII.6.14 ($\Sigma^1_2$ separation). Show that $\Pi^1_2$-$\mathsf{CA}_0$ is equivalent over $\mathsf{ACA}_0$ to the $\Sigma^1_2$ *separation principle*:

$$\neg\exists n\,(\varphi(n,1) \wedge \varphi(n,0)) \rightarrow \exists X\,\forall n\,((\varphi(n,1) \rightarrow n \in X) \wedge (\varphi(n,0) \rightarrow n \notin X))$$

where $\varphi(n,i)$ is any $\Sigma^1_2$ formula in which $X$ does not occur freely.

Our next theorem concerns $\Sigma^1_{k+3}$ choice schemes, $0 \leq k < \omega$. The theorem will be proved under the assumption $\exists X\,\forall Y\,(Y \in \mathrm{L}(X))$. We first need the following lemma which is analogous to lemma VII.6.7.

LEMMA VII.6.15 ($\Sigma^1_{k+3}$ uniformization). *Let $\varphi(Y)$ be a $\Sigma^1_{k+3}$ formula with a distinguished free set variable $Y$. Assume that $X$ does not occur freely in $\varphi(Y)$. Then we can find a $\Sigma^1_{k+3}$ formula $\widehat{\varphi}(X,Y)$ such that $\Sigma^1_{k+2}$-$\mathsf{AC}_0$ plus $\forall Y\,(Y \in \mathrm{L}(X))$ proves*

(4) $\forall Y\,(\widehat{\varphi}(X,Y) \rightarrow \varphi(Y))$,
(5) $\forall Z\,(\varphi(Z) \rightarrow \exists Y\,\widehat{\varphi}(X,Y))$,
(6) $\forall Y\,\forall Z\,((\widehat{\varphi}(X,Y) \wedge \widehat{\varphi}(X,Z)) \rightarrow Y = Z)$.

PROOF. We proceed as in the second proof of lemma VII.6.7. Write $\varphi(Y)$ as $\exists W\,\psi(Y \oplus W)$ where $\psi(Y)$ is $\Pi^1_{k+2}$. Let $\widehat{\psi}(X,Y)$ be the formula

$$\exists W\,(\forall Z\,(Z \leq^{\mathrm{L}(X)} Y \leftrightarrow \exists n\,(Z = (W)_n)) \wedge \forall n\,(\psi((W)_n) \leftrightarrow (W)_n = Y)).$$

We reason in $\Sigma^1_{k+2}$-$\mathsf{AC}_0$. By $\Sigma^1_{k+2}$ choice, the subformula

$$\forall n\,(\psi((W)_n) \leftrightarrow (W)_n = Y)$$

is equivalent to a $\Sigma^1_{k+3}$ formula. Hence by sublemma VII.6.8, $\widehat{\psi}(X,Y)$ is also equivalent to a $\Sigma^1_{k+3}$ formula. Clearly we have $\forall Y\,(\widehat{\psi}(X,Y) \rightarrow \psi(Y))$ and $\forall Y\,\forall Z\,((\widehat{\psi}(X,Y) \wedge \widehat{\psi}(X,Z)) \rightarrow Y = Z)$. Our assumption $\forall Y\,(Y \in \mathrm{L}(X))$ implies $\forall Z\,(\psi(Z) \rightarrow \exists Y\,\widehat{\psi}(X,Y))$. Setting $\widehat{\varphi}(X,Y) \equiv \exists W\,\widehat{\psi}(X, Y \oplus W)$ we obtain (4), (5) and (6). This completes the proof of lemma VII.6.15. $\square$

We are now ready to present our main result concerning $\Sigma^1_{k+3}$ choice schemes.

Theorem VII.6.16 ($\Sigma^1_{k+3}$ choice schemes). *The following is provable in* $\mathsf{ATR}_0$. *Assume* $\exists X \forall Y\, (Y \in \mathrm{L}(X))$. *Then*:

1. $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ *is equivalent to* $\Delta^1_{k+3}$-$\mathsf{CA}_0$.
2. $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ *is equivalent to* $\Delta^1_{k+3}$-$\mathsf{CA}_0$ *plus* $\Sigma^1_{k+3}$-$\mathsf{IND}$.
3. *Strong* $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ *is equivalent to* $\Pi^1_{k+3}$-$\mathsf{CA}_0$.
4. $\Sigma^1_\infty$-$\mathsf{DC}_0$ $(= \bigcup_{k<\omega} \Sigma^1_k$-$\mathsf{DC}_0)$ *is equivalent to* $\Pi^1_\infty$-$\mathsf{CA}_0$.

Proof. Parts 1, 2 and 3 are proved exactly as for theorem VII.6.9 except that $\Sigma^1_2$, $\Pi^1_2$, $\Delta^1_2$ are replaced by $\Sigma^1_{k+3}$, $\Pi^1_{k+3}$, $\Delta^1_{k+3}$ and lemma VII.6.7 is replaced by lemma VII.6.15. Part 4 follows immediately from part 3. □

Applying the above theorem to $\omega$-models and $\beta$-models, we obtain the following corollaries.

Corollary VII.6.17. *Any* $\omega$*-model of* $\Delta^1_{k+3}$-$\mathsf{CA}_0$ *plus* $\exists X \forall Y\, (Y \in \mathrm{L}(X))$ *is an* $\omega$*-model of* $\Sigma^1_{k+3}$-$\mathsf{DC}_0$. *Any model of* $\Pi^1_{k+3}$-$\mathsf{CA}_0$ *plus* $\exists X \forall Y\, (Y \in \mathrm{L}(X))$ *is a model of strong* $\Sigma^1_{k+3}$-$\mathsf{DC}_0$.

Proof. This follows immediately from VII.6.16.2 and VII.6.16.3 since $\Sigma^1_{k+3}$-$\mathsf{IND}$ is true in all $\omega$-models. □

Corollary VII.6.18. *Assume* $X \subseteq \omega$ *and let* $\alpha$ *be an ordinal.*

1. $\mathrm{L}_\alpha(X) \models \Delta^1_{k+3}$-$\mathsf{CA}^{\mathrm{set}}_0$ *if and only if* $\mathrm{L}_\alpha(X) \models \Sigma^1_{k+3}$-$\mathsf{DC}^{\mathrm{set}}_0$.
2. $\mathrm{L}_\alpha(X) \models \Pi^1_{k+3}$-$\mathsf{CA}^{\mathrm{set}}_0$ *if and only if* $\mathrm{L}_\alpha(X) \models$ *strong* $\Sigma^1_{k+3}$-$\mathsf{DC}^{\mathrm{set}}_0$.

Proof. It follows from lemma VII.4.21 that if $\mathrm{L}_\alpha(X) \models \mathsf{ATR}^{\mathrm{set}}_0$ then $\mathrm{L}_\alpha(X) \models \mathrm{V} = \mathrm{HCL}(X)$, hence $\mathrm{L}_\alpha(X) \models \forall Y\, (Y \in \mathrm{L}(X))$. Therefore, parts 1 and 2 follow immediately from VII.6.16.2 and VII.6.16.3. □

Corollary VII.6.19. *The minimum* $\beta$*-model of* $\Delta^1_{k+3}$-$\mathsf{CA}_0$ *satisfies* $\Sigma^1_{k+3}$-$\mathsf{DC}_0$. *The minimum* $\beta$*-model of* $\Pi^1_{k+3}$-$\mathsf{CA}_0$ *satisfies strong* $\Sigma^1_{k+3}$-$\mathsf{DC}_0$. *The minimum* $\beta$*-model of* $\Pi^1_\infty$-$\mathsf{CA}_0$ *satisfies* $\Sigma^1_\infty$-$\mathsf{DC}_0$.

Proof. This follows easily from theorem VII.5.17 and corollary VII.6.18. □

We now use theorem VII.6.16 to obtain some conservation theorems (definition VII.5.12) for $\Sigma^1_{k+3}$ choice schemes.

Theorem VII.6.20 (conservation theorems). *Assume* $0 \leq k < \omega$.

1. $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ *is conservative over* $\Delta^1_{k+3}$-$\mathsf{CA}_0$ *for* $\Pi^1_4$ *sentences.*
2. $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ *is conservative over* $\Delta^1_{k+3}$-$\mathsf{CA}_0$ *plus* $\Sigma^1_{k+3}$-$\mathsf{IND}$ *for* $\Pi^1_4$ *sentences.*
3. *Strong* $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ *is conservative over* $\Pi^1_{k+3}$-$\mathsf{CA}_0$ *for* $\Pi^1_4$ *sentences.*

Proof. Parts 1 and 3 are immediate from theorem VII.6.16 and corollary VII.5.11 (see also definition VII.5.12). For part 2, let $\psi$ be a $\Pi^1_4$ sentence which is not provable from $\Delta^1_{k+3}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+3}$-$\mathsf{IND}$. Let $M'$ be a model of $\Delta^1_{k+3}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+3}$-$\mathsf{IND}$ plus $\neg\psi$. Write $\neg\psi$ as $\exists X \forall Y\, \varphi(X, Y)$

where $\varphi(X, Y)$ is $\Sigma^1_2$. Let $X \in M'$ be such that $M'$ satisfies $\forall Y\, \varphi(X, Y)$. Let $M \subseteq_\omega M'$ consist of all $Y \in M$ such that $M' \models Y \in \mathrm{L}(X)$. By theorem VII.5.10, $M$ satisfies $\Delta^1_{k+3}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+3}$-$\mathsf{IND}$ plus $\forall Y\, \varphi(X, Y)$ plus $\forall Y\, (Y \in \mathrm{L}(X))$. By theorem VII.6.16.2 it follows that $M$ satisfies $\Sigma^1_{k+3}$-$\mathsf{DC}_0$. Clearly $M$ satisfies $\neg\psi$ so by the soundness theorem, $\psi$ is not provable from $\Sigma^1_{k+3}$-$\mathsf{DC}_0$. This completes the proof. □

REMARK VII.6.21. In chapter IX we shall see that $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ is conservative over $\Pi^1_{k+2}$-$\mathsf{CA}_0$ for $\Pi^1_4$ sentences. This strengthens part 1 of the above theorem VII.6.20. Also in chapter IX, we shall see that the consistency of $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ is provable from $\Pi^1_{k+2}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+3}$-$\mathsf{IND}$. Hence $\Sigma^1_{k+3}$-$\mathsf{IND}$ is not provable from $\Sigma^1_{k+3}$-$\mathsf{AC}_0$, even if we assume $\forall Y\, (Y \in \mathrm{L}(\emptyset))$. It follows that the assumption $\Sigma^1_{k+3}$-$\mathsf{IND}$ cannot be dropped from VII.6.16.2 or VII.6.20.2.

EXERCISE VII.6.22 (more conservation theorems). Assume $0 \leq k \leq m \leq n \leq \infty$. Show that $T'_0$ is conservative over $T_0$ for $\Pi^1_4$ sentences, where either:

1. $T_0$ consists of $\Pi^1_{k+1}$-$\mathsf{CA}_0$ plus $\Pi^1_{m+1}$-$\mathsf{TI}_0$ plus $\Sigma^1_{n+1}$-$\mathsf{IND}$, and $T'_0$ consists of $T_0$ plus strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$; or
2. $T_0$ consists of $\Delta^1_{k+2}$-$\mathsf{CA}_0$ plus $\Pi^1_{m+1}$-$\mathsf{TI}_0$ plus $\Sigma^1_{n+2}$-$\mathsf{IND}$, and $T'_0$ consists of $T_0$ plus $\Sigma^1_{k+2}$-$\mathsf{DC}_0$.

EXERCISE VII.6.23 ($\omega$-model conservation theorems). Assume that $0 \leq k \leq m \leq \infty$. Suppose that either:

1. $T_0$ consists of $\Pi^1_{k+1}$-$\mathsf{CA}_0$ plus $\Pi^1_{m+1}$-$\mathsf{TI}_0$, and $T'_0$ consists of $T_0$ plus strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$; or
2. $T_0$ consists of $\Delta^1_{k+2}$-$\mathsf{CA}_0$ plus $\Pi^1_{m+1}$-$\mathsf{TI}_0$, and $T'_0$ consists of $T_0$ plus $\Sigma^1_{k+2}$-$\mathsf{DC}_0$.

Show that any $\Pi^1_4$ sentence which is true in all $\omega$-models of $T'_0$ is true in all $\omega$-models of $T_0$.

EXERCISE VII.6.24 ($\beta$-model conservation theorems). Assume $0 \leq k \leq \infty$. Suppose that either:

1. $T_0 = \Pi^1_{k+1}$-$\mathsf{CA}_0$ and $T'_0 =$ strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$ ; or
2. $T_0 = \Delta^1_{k+2}$-$\mathsf{CA}_0$ and $T'_0 = \Sigma^1_{k+2}$-$\mathsf{DC}_0$.

Show that any $\Pi^1_4$ sentence which is true in all $\beta$-models of $T_0$ is true in all $\beta$-models of $T'_0$.

**Notes for §VII.6.** The $\Sigma^1_k$ choice scheme and the $\Sigma^1_k$ dependent choice scheme (parts 1 and 3 of definition VII.6.1) originated with Kreisel [150, 151]. Our strong $\Sigma^1_k$ dependent choice scheme (part 4 of definition VII.6.1) appears to be new. Theorem VII.6.9 concerning $\Sigma^1_2$ choice schemes is inspired by an unpublished result of Mansfield; see Friedman

[64, theorem 6]. Results such as theorem VII.6.16 on $\Sigma^1_{k+3}$ choice schemes are probably well known, but we have been unable to find bibliographical references for them. Our sharp formulations VII.6.20–VII.6.24 in terms of conservation results are probably new.

## VII.7. $\beta$-Model Reflection

In this final section of chapter VII we consider one more topic: $\beta$-model reflection principles. An important consequence of the ideas in this section is that for all $k$,

$$\Sigma^1_{k+1}\text{-}\mathsf{DC}_0 < \text{strong } \Sigma^1_{k+1}\text{-}\mathsf{DC}_0 < \Sigma^1_{k+2}\text{-}\mathsf{DC}_0$$

where $<$ denotes increasing logical strength (theorem VII.7.7).

Our results are most conveniently stated in terms of the notion of $\beta_k$-model, $1 \leq k < \omega$.

Definition VII.7.1 ($\beta_k$-models). Assume $0 \leq k < \omega$. A *$\beta_k$-model* is an $\omega$-model $M$ such that for all $\Sigma^1_k$ sentences $\varphi$ with parameters from $M$, $\varphi$ is true if and only if $M \models \varphi$.

Thus a $\beta_1$-model is the same thing as a $\beta$-model. Also, a $\beta_0$-model is the same thing as an $\omega$-model.

We shall now formalize the notion of $\beta_k$-model within $\mathsf{RCA}_0$. The following definition within $\mathsf{RCA}_0$ is actually an infinite set of definitions, one for each $k$. Fix a universal lightface $\Pi^0_1$ formula

$$\pi(e, m_1, m_2, X_1, X_2, \ldots, X_k, X_{k+1}, X_{k+2})$$

with exactly the displayed free variables (definition VII.1.3). Let $\varphi_k(e, m, X, Y)$ be the $\Sigma^1_k$ formula

$$\exists X_1 \forall X_2 \cdots X_k \pm \exists n\, \pi(e, m, n, X_1, X_2, \ldots, X_k, X, Y)$$

where $\pm\exists$ is $\exists$ if $k$ is even, $\neg\exists$ if $k$ is odd. Thus $\varphi_k(e, m, X, Y)$ is in some sense a universal lightface $\Sigma^1_k$ formula with free variables $e, m, X, Y$.

Definition VII.7.2 (countable coded $\beta_k$-models). Within $\mathsf{RCA}_0$, we define a *countable coded $\beta_k$-model* to be a countable coded $\omega$-model $M$ (definition VII.2.1) such that for all $e, m \in \mathbb{N}$ and $X, Y \in \mathcal{S}_M$, $\varphi_k(e, m, X, Y)$ if and only if $M \models \varphi_k(e, m, X, Y)$.

Lemma VII.7.3. *Let $\psi(m_1, \ldots, m_i, X_1, \ldots, X_j)$ be any $\Pi^1_{k+1}$ formula with exactly the displayed free variables. The following is provable in $\mathsf{ACA}_0$. Let $M$ be a countable coded $\beta_k$-model. For all $m_1, \ldots, m_i \in \mathbb{N}$ and $X_1, \ldots, X_j \in M$, if $\psi(m_1, \ldots, m_i, X_1, \ldots, X_j)$ is true then $M \models \psi(m_1, \ldots, m_i, X_1, \ldots, X_j)$.*

PROOF. For $k = 0$ the result is trivial, so assume $k \geq 1$. Then by lemma VII.2.4 we have $M \models \mathsf{ACA}_0$. Let $e < \omega$ be such that $\mathsf{ACA}_0$ proves

$$\psi(m_1, \ldots, m_i, X_1, \ldots, X_j) \leftrightarrow \forall Y \varphi_k(e, \langle m_1, \ldots, m_i \rangle, X_1 \oplus \cdots \oplus X_j, Y).$$

The desired conclusion follows easily. □

THEOREM VII.7.4. *Assume $0 \leq k < \omega$. Over $\mathsf{ACA}_0$, strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$ is equivalent to the following assertion. For all $X \subseteq \mathbb{N}$, there exists a countable coded $\beta_{k+1}$-model $M$ such that $X \in M$.*

PROOF. First, assume strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$. Given $X \subseteq \mathbb{N}$, let $\eta(n, Y, Z)$ be the $\Sigma^1_{k+1}$ formula

$$\exists e \, \exists m \, (n = (e, m) \wedge \varphi_{k+1}(e, m, X \oplus Y, Z)).$$

By strong $\Sigma^1_{k+1}$-dependent choice, let $W$ be such that

$$\forall n \, \forall Z \, (\eta(n, (W)^n, Z) \rightarrow \eta(n, (W)^n, (W)_n)).$$

It is straightforward to check that $W$ is a code for a countable $\beta_{k+1}$-model $M$ such that $X \in M$. (Compare the proof of lemma VII.2.9.)

For the converse we proceed as in the proof of part 4 of theorem VII.6.9. Reasoning in $\mathsf{ACA}_0$, assume that for all $X$ there exists a countable coded $\beta_{k+1}$-model which contains $X$. Let $\eta(n, X, Y, Z)$ be a $\Sigma^1_{k+1}$ formula with only the displayed free variables. Given $X$, let $W$ be a code for a countable $\beta_{k+1}$-model $M$ such that $X \in M$. Define $f : \mathbb{N} \rightarrow \mathbb{N}$ by $f(n) =$ least $j$ such that

$$M \models \eta(n, X, \{(i, m) \colon (i, f(m)) \in W \wedge m < n\}, (W)_j)$$

if such $j$ exists, $f(n) = 0$ otherwise. Setting

$$W' = \{(i, n) \colon (i, f(n)) \in W\},$$

we see that for all $n$,

$$M \models \forall Z \, (\eta(n, X, (W')^n, Z) \rightarrow \eta(n, X, (W')^n, (W')_n)).$$

Since $M$ is a $\beta_{k+1}$-model, it follows by lemma VII.7.3 that the above formula is true for all $n$. This proves strong $\Sigma^1_{k+1}$ dependent choice and completes the proof of theorem VII.7.4. □

DEFINITION VII.7.5 ($\beta_k$-model reflection). Assume $0 \leq k \leq m < \omega$. Within $\mathsf{ACA}_0$, we define *$\beta_k$-model reflection for $\Sigma^1_m$ formulas* to be the scheme

$$\forall X \, (\theta(X) \rightarrow \exists \text{countable coded } \beta_k\text{-model } M \text{ such that } X \in M \text{ and } M \models \theta(X))$$

where $\theta(X)$ is any $\Sigma^1_m$ formula with no free set variables other than $X$.

The situation as regards *$\omega$-model reflection*, i.e., $\beta_0$-model reflection, will be considered separately in §VIII.5. For $\beta_{k+1}$-model reflection we have the following result.

Theorem VII.7.6. *The following is provable in* $\mathsf{ACA}_0$. *Assume* $0 \leq k < \omega$.

1. *Strong* $\Sigma^1_{k+1}$-$\mathsf{DC}_0$ *is equivalent to* $\beta_{k+1}$*-model reflection for* $\Sigma^1_{k+3}$ *formulas.*
2. $\Sigma^1_{k+2}$-$\mathsf{DC}_0$ *is equivalent to* $\beta_{k+1}$*-model reflection for* $\Sigma^1_{k+4}$ *formulas.*

Proof. Note first that for any $\Pi^1_{k+2}$ sentence $\psi$ with parameters in a $\beta_{k+1}$-model $M$, we have by lemma VII.7.3 $\psi \rightarrow (M \models \psi)$. This observation combines with theorem VII.7.4 to easily yield part 1.

For part 2, assume $\Sigma^1_{k+2}$-$\mathsf{DC}_0$. In particular strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$ holds, so by theorem VII.7.4 we have $\forall Y\, \exists M$ ($M$ is a countable coded $\beta_{k+1}$-model such that $Y \in M$). Now let $X_0$ be such that $\theta(X_0)$ holds where $\theta(X)$ is $\Sigma^1_{k+4}$. Write $\theta(X)$ as $\exists V\, \forall Y\, \exists Z\, \psi(V, X, Y, Z)$ where $\psi$ is $\Pi^1_{k+1}$. Let $V_0$ be such that $\forall Y\, \exists Z\, \psi(V_0, X_0, Y, Z)$ holds. Let $\eta(V, X, Y, Z)$ say that $Z$ is a code for a countable $\beta_{k+1}$-model and $\forall m\, \exists j\, \psi(V, X, (Y)_m, (Z)_j)$. Thus $\eta(V, X, Y, Z)$ is $\Pi^1_{k+1}$ and $\forall Y\, \exists Z\, \eta(V_0, X_0, Y, Z)$ holds. By $\Sigma^1_{k+2}$ dependent choice, let $W$ be such that $((W)_0)_0 = X_0$ and $((W)_0)_1 = V_0$ and $\forall n\, \eta(V_0, X_0, (W)_n, (W)_{n+1})$. Setting $W' = \{(i, (j, n))\colon ((i, j), n) \in W\}$, we see that $W'$ is a code for a countable $\beta_{k+1}$-model $M'$ such that $X_0 \in M'$ and $V_0 \in M'$ and $M' \models \forall Y\, \exists Z\, \psi(V_0, X_0, Y, Z)$. This proves $\beta_{k+1}$-model reflection for $\Sigma^1_{k+4}$-formulas.

For the converse, assume $\beta_{k+1}$-model reflection for $\Sigma^1_{k+4}$ formulas. Suppose $\forall n\, \forall Y\, \exists Z\, \eta(n, Y, Z)$ where $\eta(n, Y, Z)$ is $\Sigma^1_{k+2}$. Let $W$ be a code for a $\beta_{k+1}$-model $M$ such that $M$ contains the parameters of $\eta(n, Y, Z)$ and $M \models \forall n\, \forall Y\, \exists Z\, \eta(n, Y, Z)$. Define $f : \mathbb{N} \rightarrow \mathbb{N}$ by $f(n) =$ least $j$ such that

$$M \models \eta(n, \{(i, m)\colon (i, f(m)) \in W \wedge m < n\}, (W)_j).$$

Setting $W' = \{(i, n)\colon (i, f(n)) \in W\}$, we see that $M \models \eta(n, (W')^n, (W')_n)$ for all $n$. Since $M$ is a $\beta_{k+1}$-model, it follows that $\forall n\, \eta(n, (W')^n, (W')_n)$ is true. This proves $\Sigma^1_{k+2}$ dependent choice and completes the proof of theorem VII.7.6. □

Theorem VII.7.7. *Assume* $0 \leq k < \omega$.

1. $\Sigma^1_{k+2}$-$\mathsf{DC}_0$ *proves the existence of a countable coded* $\beta_{k+1}$*-model of strong* $\Sigma^1_{k+1}$-$\mathsf{DC}_0$.
2. *Strong* $\Sigma^1_{k+1}$-$\mathsf{DC}_0$ *proves the existence of a countable coded* $\beta_{k+1}$*-model of* $\Sigma^1_{k+1}$-$\mathsf{DC}_0$.

Proof. First assume $\Sigma^1_{k+2}$-$\mathsf{DC}_0$. In particular strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$ holds, so by theorem VII.7.4 we have $\forall X\, \exists Y$ ($Y$ is a code for a countable $\beta_{k+1}$-model $M$ such that $X \in M$). Applying $\Sigma^1_{k+1}$-$\mathsf{DC}_0$ we obtain $Z$ such that $\forall n$ ($(Z)_n$ is a code for a countable $\beta_{k+1}$-model $M_n$ such that $(Z)^n \in M_n$). Setting $Z' = \{(i, (j, n))\colon ((i, j), n) \in Z\}$ we see that $Z'$ is a code for the countable $\beta_{k+1}$-model $M' = \bigcup_{n \in \mathbb{N}} M_n$. By construction $M' \models \forall X\, \exists Y$

($Y$ is a code for a countable $\beta_{k+1}$-model $M$ such that $X \in M$). Hence by theorem VII.7.4, $M' \models$ strong $\Sigma^1_{k+1}$-DC$_0$. This establishes part 1.

For part 2, assume strong $\Sigma^1_{k+1}$-DC$_0$. By theorem VII.7.4 there exists a countable coded $\beta_{k+1}$-model $M$. We claim that $M \models \Sigma^1_{k+1}$-DC$_0$. Suppose that $M \models \forall n \forall X \exists Y \eta(n, X, Y)$ where $\eta(n, X, Y)$ is $\Sigma^1_{k+1}$. Let $W$ be a code for $M$ and define $f : \mathbb{N} \to \mathbb{N}$ by $f(n) =$ least $j$ such that

$$\eta(n, \{(i, m) : (i, f(m)) \in W \wedge m < n\}, (W)_j\}$$

holds. Setting $W' = \{(i, n) : (i, f(n)) \in W\}$ we get

$$\forall n \, \eta(n, (W')^n, (W')_n),$$

hence $\exists Z \forall n \, \eta(n, (Z)^n, (Z)_n)$. Since $M$ is a $\beta_{k+1}$-model it follows that $M \models \exists Z \forall n \, \eta(n, (Z)^n, (Z)_n)$. This proves the claim and completes the proof of theorem VII.7.7. □

COROLLARY VII.7.8. *Assume* $0 \leq k < \omega$.

1. $\Delta^1_{k+3}$-CA$_0$ *plus* $\Sigma^1_{k+3}$-IND *proves the existence of a countable coded* $\beta_2$*-model of* $\Pi^1_{k+2}$-CA$_0$.
2. $\Pi^1_{k+2}$-CA$_0$ *proves the existence of a countable coded* $\beta_2$*-model of* $\Delta^1_{k+2}$-CA$_0$.

PROOF. The sentence

$$\exists \text{countable coded } \beta_2\text{-model of strong } \Sigma^1_{k+2}\text{-DC}_0$$

is $\Sigma^1_3$ and, by VII.7.7.1, provable in $\Sigma^1_{k+3}$-DC$_0$. Hence by the conservation theorem VII.6.20.2, this same sentence is provable in $\Delta^1_{k+3}$-CA$_0$ plus $\Sigma^1_{k+3}$-IND. Part 1 follows in view of VII.6.6.3. The proof of part 2 is similar using VII.7.7.2, VII.6.20.3, VII.6.9.3, VII.6.6.1 and VII.6.6.2. □

COROLLARY VII.7.9. *Assume* $0 \leq k < \omega$.

1. $\Delta^1_{k+2}$-CA$_0$ *plus* $\Sigma^1_{k+2}$-IND *proves the existence of a countable coded* $\beta$*-model of* $\Pi^1_{k+1}$-CA$_0$.
2. $\Pi^1_{k+1}$-CA$_0$ *proves the existence of a countable coded* $\beta$*-model of* $\Delta^1_{k+1}$-CA$_0$.

PROOF. For $k \geq 1$ this is immediate from corollary VII.7.8. For $k = 0$ the result follows easily from corollary VII.7.8 using lemma VII.6.6 and parts 2 and 4 of theorem VII.6.9. □

COROLLARY VII.7.10 (minimum $\beta$-models). *For* $X \subseteq \omega$ *and* $0 \leq k < \omega$ *we have*

$$\alpha^{\Pi}_{k+1}(X) < \alpha^{\Delta}_{k+2}(X) < \alpha^{\Pi}_{k+2}(X)$$

*where* $\alpha^{\Pi}_{k+1}(X)$ *and* $\alpha^{\Delta}_{k+2}(X)$ *are the ordinals of the minimum* $\beta$*-models of* $\Pi^1_{k+1}$-CA$_0$ *and* $\Delta^1_{k+2}$-CA$_0$ *containing* $X$, *respectively.*

PROOF. This is immediate from corollary VII.7.9 and theorem VII.5.17. □

Remark VII.7.11. In chapter IX we shall see that $\Delta^1_{k+3}$-$\mathsf{CA}_0$ is conservative over $\Pi^1_{k+2}$-$\mathsf{CA}_0$ for $\Pi^1_4$ sentences (corollary IX.4.12). Hence the assumption of $\Sigma^1_{k+3}$-$\mathsf{IND}$ in corollary VII.7.8 cannot be dropped.

Exercises VII.7.12. In this set of exercises we consider $\beta$-models of $\Pi^1_{k+1}$-$\mathsf{TR}_0$, $0 \leq k < \omega$. (See also exercise VII.5.20.)

Prove the following:

1. $\Delta^1_{k+2}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+2}$-$\mathsf{TI}_0$ together imply $\Pi^1_{k+1}$-$\mathsf{TR}_0$. (The proof is straightforward, using transfinite induction to iterate $\Pi^1_{k+1}$ comprehension along a given countable well ordering.)
2. $\Sigma^1_{k+2}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+2}$-$\mathsf{TI}_0$ proves the existence of a countable coded $\beta_{k+1}$-model of $\Pi^1_{k+1}$-$\mathsf{TR}_0$. (Hint: Use the previous exercise plus $\beta_{k+1}$-model reflection.)
3. $\Delta^1_{k+3}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+3}$-$\mathsf{TI}_0$ proves the existence of a countable coded $\beta_2$-model of $\Pi^1_{k+2}$-$\mathsf{TR}_0$. (Hint: Use the previous exercise plus results from §§VII.5 and VII.6.)
4. $\Delta^1_{k+2}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+2}$-$\mathsf{TI}_0$ proves the existence of a countable coded $\beta$-model of $\Pi^1_{k+1}$-$\mathsf{TR}_0$.
5. For any $X \subseteq \omega$ we have
$$\alpha^{\Pi}_{k+1}(X) < \alpha^{\Pi^*}_{k+1}(X) < \alpha^{\Delta}_{k+2}(X)$$
where $\alpha^{\Pi^*}_{k+1}$ is the ordinal of the minimum $\beta$-model of $\Pi^1_{k+1}$-$\mathsf{TR}_0$ containing $X$.

Remark VII.7.13. In exercises VIII.4.24 we shall see that $\Pi^1_{k+1}$-$\mathsf{TR}_0$ proves the existence of a countable coded $\omega$-model of $\Sigma^1_{k+2}$-$\mathsf{DC}_0$. Hence the assumption of $\Sigma^1_{k+2}$-$\mathsf{TI}_0$ in exercise VII.7.12 cannot be dropped.

**Notes for §VII.7.** Results such as corollary VII.7.10 on minimum $\beta$-models of $\Delta^1_k$-$\mathsf{CA}_0$ and $\Sigma^1_k$-$\mathsf{CA}_0$ are probably very plausible to students of Jensen's fine structure theory [131]; see also our notes at the end of §VII.5. However, they do not seem to be in the previously published literature. The other results of this section are probably new.

## VII.8. Conclusions

In this chapter we have studied $\beta$-models. We have seen that every $\beta$-model is automatically a model of $\mathsf{ATR}_0$ and indeed of $\Pi^1_\infty$-$\mathsf{TI}_0$, but not of $\Pi^1_1$-$\mathsf{CA}_0$ (§VII.2). On the other hand, $\Pi^1_1$-$\mathsf{CA}_0$ has a minimum $\beta$-model obtained by iterating the hyperjump $\omega$ times (§VII.1). More generally, for all $k \geq 2$, $\Pi^1_k$-$\mathsf{CA}_0$ and $\Delta^1_k$-$\mathsf{CA}_0$ have minimum $\beta$-models (§VII.5) which are described in terms of initial segments of the Gödel's hierarchy

of constructible sets. These models are all distinct (§VII.7) and satisfy appropriate forms of the axiom of choice (§VII.6). The proofs of these results yield conservation theorems which are best possible.

An important role is played by $\beta$-model reflection. $\Pi^1_1$-$\mathsf{CA}_0$ is equivalent to the existence of sufficiently many countable coded $\beta$-models (§VII.2). More generally, for each $k \geq 1$, strong $\Sigma^1_k$ dependent choice is equivalent to the existence of sufficiently many countable coded $\beta_k$-models (§VII.7).

Set-theoretic methods have been very useful in this chapter. Our coding of hereditarily countable sets by well founded trees works well in $\mathsf{ATR}_0$ (§VII.3) and leads to a good theory of constructible sets, including a $\Pi^1_1$-$\mathsf{CA}_0$ version of the Shoenfield absoluteness lemma (§VII.4).

Chapter VIII

# $\omega$-MODELS

An *$\omega$-model* is an $L_2$-model $M$ whose first order part is standard. Thus $M$ may be viewed simply as a collection of sets of natural numbers, serving as the range of the set variables in $L_2$.

The purpose of this chapter is to study countable $\omega$-models of subsystems of second order arithmetic. We concentrate on the subsystems which are by now familiar: $\mathsf{RCA}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\Sigma^1_1$-$\mathsf{AC}_0$ and related systems, $\mathsf{ATR}_0$, $\Pi^1_\infty$-$\mathsf{TI}_0$, and $\Pi^1_1$-$\mathsf{CA}_0$. We shall also obtain some general results about $\omega$-models of fairly arbitrary $L_2$-theories, which may be stronger than $\Pi^1_1$-$\mathsf{CA}_0$.

In §VIII.1 we study countable $\omega$-models of $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$. We point out that an $\omega$-model of $\mathsf{RCA}_0$ is essentially the same thing as an ideal of Turing degrees. An $\omega$-model of $\mathsf{ACA}_0$ is then characterized by the additional property of closure under Turing jump. In particular, each of $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$ has a minimum (i.e., unique smallest) $\omega$-model. The minimum $\omega$-model of $\mathsf{RCA}_0$ is the collection REC of recursive sets, and the minimum $\omega$-model of $\mathsf{ACA}_0$ is the collection ARITH of arithmetical sets. By use of countable coded $\omega$-models, we show that $\mathsf{ACA}_0$ proves the consistency of $\mathsf{RCA}_0$.

In §VIII.2 we consider countable $\omega$-models of $\mathsf{WKL}_0$. We show that any such model has a proper $\omega$-submodel which is again a model of $\mathsf{WKL}_0$. Indeed, we can find such a submodel which is coded in the original model. By further use of countable coded $\omega$-models, we show that the consistency of $\mathsf{WKL}_0$ is provable in $\mathsf{ACA}_0$. We go on to show that $\mathsf{WKL}_0$ has countable coded $\omega$-models which are "close to recursive," in various senses of that phrase. In particular, although REC is not itself an $\omega$-model of $\mathsf{WKL}_0$, it is the intersection of all such models.

In §VIII.3 we develop hyperarithmetical theory in a form needed for later applications. We show that the principal axiom of $\mathsf{ATR}_0$ is equivalent to the assertion that the Turing jump operator can be iterated along any countable well ordering starting with any set. Hyperarithmetical sets are those which can be obtained by iterating the Turing jump operator along a recursive well ordering starting with the empty set. The collection of hyperithmetical sets is denoted HYP. We show that $X \in \mathrm{HYP}$ if and only

if $X$ is $\Delta^1_1$ definable. By the method of pseudohierarchies (compare §V.4), we show that $\Sigma^1_1$ definability over HYP is equivalent to $\Pi^1_1$ definability. Thus HYP is an $\omega$-model of $\Delta^1_1$ comprehension but not $\Pi^1_1$ comprehension. We show that all of these results are, in a sense, provable in $\mathsf{ATR}_0$.

In §§VIII.4, VIII.5 and VIII.6 we study $\omega$-models of $\Delta^1_1$-$\mathsf{CA}_0$, $\mathsf{ATR}_0$, and stronger systems. The countable $\omega$-model HYP plays a key role. Some of the results can be understood in terms of the following analogy:

$$\frac{\mathsf{RCA}_0}{\Delta^1_1\text{-}\mathsf{CA}_0} = \frac{\mathsf{WKL}_0}{\mathsf{ATR}_0} = \frac{\mathrm{REC}}{\mathrm{HYP}}.$$

For example, just as REC is the minimum $\omega$-model of $\mathsf{RCA}_0$, so HYP is the minimum $\omega$-model of $\Delta^1_1$-$\mathsf{CA}_0$ and of related systems. Similarly, although HYP is not itelf a model of $\mathsf{ATR}_0$, it is the intersection of all countable $\beta$-models of $\mathsf{ATR}_0$. Furthermore, for any recursively axiomatizable $\mathrm{L}_2$-theory $S \supseteq \Delta^1_1$-$\mathsf{CA}_0$, HYP is the intersection of all countable $\omega$-models of $S$. If in addition $S \supseteq \mathsf{ATR}_0$, then for any countable $\omega$-model $M$ of $S$, $\mathrm{HYP}^M$ is the intersection of all countable $\omega$-submodels of $M$ which satisfy $S$.

We also obtain some results which are not covered by the above analogy. In §VIII.4 we use pseudohierarchies and countable coded $\omega$-models to show that $\mathsf{ATR}_0$ proves the consistency of $\Sigma^1_1$-$\mathsf{DC}_0$ plus full induction. In §VIII.5 we show that the transfinite induction scheme (introduced in §VII.2) is equivalent to a reflection principle for countable coded $\omega$-models. We also obtain an $\omega$-model version of Gödel's second incompleteness theorem. These theorems are then used to prove some $\omega$-model independence results. In particular, we obtain a countable $\omega$-model of $\Pi^1_1$-$\mathsf{CA}_0$ which is not a model of the transfinite induction scheme, $\Pi^1_\infty$-$\mathsf{TI}_0$. We also obtain a countable $\omega$-model of $\Sigma^1_1$-$\mathsf{AC}_0$ which is not a model of $\Sigma^1_1$-$\mathsf{DC}_0$.

Throughout this chapter, we formulate our results so as to apply not only to $\omega$-models but also, insofar as possible, to arbitrary models of the systems considered. Nevertheless, it will be clear that our methods are best suited to the study of $\omega$-models which are not $\beta$-models. Other results about $\omega$-models have been presented in chapter VII.

## VIII.1. $\omega$-Models of $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$

The formal systems $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$ were studied extensively in chapters II and III respectively. The purpose of this section is to present some simple results about models, especially $\omega$-models, of $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$. We discuss both $\omega$-submodels of given models and countable coded $\omega$-models. (Compare §§VII.1 and VII.2.) For additional information on models of $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$, see §IX.1.

We first consider models of $\mathsf{RCA}_0$.

Recall from definition VII.1.4 that $Y \leq_{\mathrm{T}} X$ if and only if $Y$ is *Turing reducible to* $X$, i.e., *recursive in* $X$. Recall also that, by definition,

$$X \oplus Y = \{2n : n \in X\} \cup \{2n+1 : n \in Y\}.$$

These definitions are made within $\mathsf{RCA}_0$.

LEMMA VIII.1.1. *Let $M'$ be a model of $\mathsf{RCA}_0$. Let $M$ be an $\omega$-submodel of $M'$. Then $M$ is a model of $\mathsf{RCA}_0$ if and only if $M$ is nonempty and closed under $\oplus$ and $\leq_{\mathrm{T}}$.*

($M$ is said to be *closed under* $\oplus$ if $X \in M$ and $Y \in M$ imply $X \oplus Y \in M$. $M$ is said to be *closed under* $\leq_{\mathrm{T}}$ if $X \in M$ and $Y \leq_{\mathrm{T}} X$ imply $Y \in M$.)

PROOF. The proof is straightforward using the fact that $Y \leq_{\mathrm{T}} X$ if and only if $Y$ is $\Delta^0_1$ in $X$. □

LEMMA VIII.1.2. *The following is provable in $\mathsf{RCA}_0$. The relation $\leq_{\mathrm{T}}$ is* transitive, *i.e., if $Z \leq_{\mathrm{T}} Y$ and $Y \leq_{\mathrm{T}} X$ then $Z \leq_{\mathrm{T}} X$.*

PROOF. The proof is straightforward using the normal form theorem II.2.7 for $\Pi^0_1$ formulas. □

THEOREM VIII.1.3 (minimum $\omega$-submodels of $\mathsf{RCA}_0$). *Let $M'$ be a model of $\mathsf{RCA}_0$. Let $X \in M'$ be given. Among all $\omega$-submodels $M$ of $M'$ such that $X \in M \models \mathsf{RCA}_0$, there exists a unique smallest one, namely that $M \subseteq_\omega M'$ which consists of all $Y$ such that $M' \models Y \leq_{\mathrm{T}} X$.*

PROOF. From lemma VIII.1.2 it is clear that $M$ is a model of $\mathsf{RCA}_0$. The rest follows from lemma VIII.1.1. □

COROLLARY VIII.1.4 (minimum $\omega$-model of $\mathsf{RCA}_0$). *There exists a minimum (i.e., unique smallest) $\omega$-model of $\mathsf{RCA}_0$, namely*

$$\mathrm{REC} = \{X \subseteq \omega : X \text{ is recursive}\}.$$

(A set $X \subseteq \omega$ is said to be *recursive* if and only if $X \leq_{\mathrm{T}} \emptyset$.)

PROOF. In the previous theorem, take $M' = P(\omega)$ and $X = \emptyset$. □

LEMMA VIII.1.5 (finite axiomatizability). *The formal systems $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$ are finitely axiomatizable.*

PROOF. Let $\pi(e, m_1, X_1)$ be a universal lightface $\Pi^0_1$ formula with exactly the displayed free variables (see definition VII.1.3). The axioms of $\mathsf{RCA}_0$ can be taken to consist of the basic axioms I.2.4(i), the pairing axiom

$$\forall X \, \forall Y \, \exists Z \, (Z = X \oplus Y),$$

$\Delta^0_1$ comprehension in the form

$$\forall m \, (\neg\pi(e_0, m, X) \leftrightarrow \pi(e_1, m, X)) \rightarrow \exists Y \, \forall m \, (m \in Y \leftrightarrow \pi(e_1, m, X)),$$

and $\Sigma^0_1$ induction in the form

$$(\neg\pi(e, 0, X) \wedge \forall m \, (\neg\pi(e, m, X) \rightarrow \neg\pi(e, m+1, X))) \rightarrow \forall m \, \neg\pi(e, m, X).$$

Then, by lemma III.1.3, the axioms of $\mathsf{ACA}_0$ can be taken to be those of $\mathsf{RCA}_0$ plus $\Sigma^0_1$ comprehension in the form

$$\exists Y\, \forall m\, (m \in Y \leftrightarrow \neg\pi(e, m, X)).$$

This proves lemma VIII.1.5. □

THEOREM VIII.1.6. *The following is provable in* $\mathsf{ACA}_0$. *Given* $X \subseteq \mathbb{N}$, *there exists a unique smallest countable coded* $\omega$*-model such that* $X \in M$ *and* $M$ *satisfies* $\mathsf{RCA}_0$. *Namely,* $M$ *consists of all* $Y \subseteq \mathbb{N}$ *such that* $Y \leq_{\mathrm{T}} X$.

PROOF. We reason within $\mathsf{ACA}_0$. By arithmetical comprehension, let $W$ be the set of triples $(m, (e_0, e_1))$ such that

$$\forall m\, (\neg\pi(e_0, m, X) \leftrightarrow \pi(e_1, m, X))$$

and $\pi(e_1, m, X)$ holds. Thus $W$ is a code of the countable $\omega$-model $M$. Clearly $X \in M$ and $M$ is included in all countable coded $\omega$-models $M'$ such that $X \in M'$ and $M'$ satisfies $\mathsf{RCA}_0$. It remains to check that $M$ itself satisfies $\mathsf{RCA}_0$. By lemma VIII.1.5 let $\varphi$ be the conjunction of the axioms of $\mathsf{RCA}_0$. By lemma VII.2.2 there exists a valuation $f : \mathrm{Sub}_M(\varphi) \to \{0, 1\}$. It remains to show that $f(\varphi) = 1$. Going back to the construction of $M$, it is straightforward to check that $M$ is closed under $\oplus$. Hence $f$(pairing axiom) $= 1$. By lemma VII.1.1 $M$ is closed under $\leq_{\mathrm{T}}$. From this it follows easily that $f(\Delta^0_1$ comprehension$) = 1$. It is also easy to check that $f(\Sigma^0_1$ induction$) = 1$. This completes the proof. □

COROLLARY VIII.1.7 (consistency of $\mathsf{RCA}_0$). $\mathsf{ACA}_0$ *proves the consistency of* $\mathsf{RCA}_0$.

PROOF. We reason within $\mathsf{ACA}_0$. Let $M$ and $f$ be as in the proof of theorem VIII.1.6. Then $M$ and $f$ form a weak model of $\mathsf{RCA}_0$ in the sense of definition II.8.9. Hence by the strong soundness theorem II.8.10 it follows that $\mathsf{RCA}_0$ is consistent. This completes the proof. □

COROLLARY VIII.1.8. *There exists a* $\Pi^0_1$ *sentence* $\psi$ *such that* $\psi$ *is provable in* $\mathsf{ACA}_0$ *but not in* $\mathsf{RCA}_0$.

PROOF. Let $\psi$ be the $\Pi^0_1$ sentence which asserts the consistency of $\mathsf{RCA}_0$. By corollary VII.1.7, $\psi$ is provable in $\mathsf{ACA}_0$. The fact that $\psi$ is not provable in $\mathsf{RCA}_0$ is just Gödel's second incompleteness theorem [94, 115, 55, 222] applied to the formal system $\mathsf{RCA}_0$. □

We now turn to models of $\mathsf{ACA}_0$.

DEFINITION VIII.1.9. The following definition is made in $\mathsf{RCA}_0$. Given $X \subseteq \mathbb{N}$, the *Turing jump of* $X$, denoted $\mathrm{TJ}(X)$, is the set of all $(m, e)$ such that $\pi(e, m, X)$ holds, if this set exists. (Here $\pi(e, m_1, X_1)$ is a fixed universal lightface $\Pi^0_1$ formula as in the proof of lemma VIII.1.5 above.)

We define iterated Turing jumps $\mathrm{TJ}(n, X)$, $n \in \omega$ by recursion on $n$ as follows: $\mathrm{TJ}(0, X) = X$ and $\mathrm{TJ}(n + 1, X) = \mathrm{TJ}(\mathrm{TJ}(n, X))$.

THEOREM VIII.1.10 (minimum $\omega$-submodels of $\mathsf{ACA}_0$). *Let $M'$ be a model of $\mathsf{ACA}_0$. Let $X \in M'$ be given. Among all $\omega$-submodels $M$ of $M'$ such that $X \in M \models \mathsf{ACA}_0$, there exists a unique smallest one, namely the $M \subseteq_\omega M'$ consisting of all $Y$ such that, for some $n \in \omega$, $M' \models Y \leq_{\mathrm{T}} \mathsf{TJ}(n, X)$.*

PROOF. Recall that $|M'|$ is the set of natural numbers of the $\mathrm{L}_2$-model $M'$. Let $M$ be the set of all $Y \in M'$ such that $Y$ is definable over $M'$ by an arithmetical formula with parameters from $|M'| \cup \{X\}$. Obviously $M$ is the smallest $\omega$-submodel of $M'$ which contains $X$ and satisfies arithmetical comprehension. It is straightforward to check that for each $Y \in M$ there exists $n \in \omega$ such that $M' \models Y \leq_{\mathrm{T}} \mathsf{TJ}(n, X)$. This completes the proof. □

COROLLARY VIII.1.11 (minimum $\omega$-model of $\mathsf{ACA}_0$). *There exists a minimum (i.e., unique smallest) $\omega$-model of $\mathsf{ACA}_0$, namely*

$$\begin{aligned}\mathrm{ARITH} &= \{X \subseteq \omega : \exists n\,(X \leq_{\mathrm{T}} \mathsf{TJ}(n, \emptyset))\} \\ &= \{X \subseteq \omega : X \text{ is arithmetical}\}.\end{aligned}$$

(A set $X \subseteq \omega$ is said to be *arithmetical* if it is definable over the standard model $(\omega, +, \cdot, 0, 1, <)$ of $\mathsf{Z}_1$.)

PROOF. In the previous theorem, take $M' = P(\omega)$ and $X = \emptyset$. □

EXERCISE VIII.1.12. Show that $\mathsf{ACA}_0$ is equivalent over $\mathsf{RCA}_0$ to the assertion that, for all $X \subseteq \mathbb{N}$, $\mathsf{TJ}(X)$ exists.

THEOREM VIII.1.13. *The following is provable in $\mathsf{ATR}_0$. Given $X \subseteq \mathbb{N}$, there exists a unique smallest countable coded $\omega$-model $M$ of $\mathsf{ACA}_0$ such that $X \in M$. Namely, $M$ consists of all $Y \subseteq \mathbb{N}$ such that $\exists n\,(Y \leq_{\mathrm{T}} \mathsf{TJ}(n, X))$.*

PROOF. By arithmetical transfinite recursion (along the standard well ordering $<$ of $\mathbb{N}$), the sequence $\langle \mathsf{TJ}(n, X) : n \in \mathbb{N} \rangle$ exists. The rest of the proof is similar to that of theorem VIII.1.6. □

COROLLARY VIII.1.14 (consistency of $\mathsf{ACA}_0$). $\mathsf{ATR}_0$ *proves the consistency of $\mathsf{ACA}_0$ plus full induction, $\Sigma^1_\infty$-IND.*

PROOF. We reason within $\mathsf{ATR}_0$. By theorem VIII.1.13 there exists a countable coded $\omega$-model $M$ of $\mathsf{ACA}_0$. By another application of arithmetical transfinite recursion, there exists a full valuation $f : \mathrm{Snt}_M \to \{0, 1\}$. (Compare definition VII.2.1.) Thus $M$ and $f$ form a countable model in the sense of definition II.8.3. It is straightforward to check that $f(\mathsf{ACA}_0) = 1$ and that $f(\varphi) = 1$ for all instances $\varphi$ of induction. Hence by the soundness theorem II.8.8 it follows that $\mathsf{ACA}_0$ plus full induction is consistent. This completes the proof. □

COROLLARY VIII.1.15. *There exists a $\Pi^0_1$ sentence $\psi$ such that $\psi$ is provable in $\mathsf{ATR}_0$, but not in $\mathsf{ACA}_0$ plus full induction.*

PROOF. This follows from corollary VIII.1.14 just as VIII.1.8 followed from VIII.1.7. □

REMARK VIII.1.16. We shall see in §VIII.2 that $\mathsf{ACA}_0$ proves the consistency of $\mathsf{WKL}_0$. We shall see in §VIII.4 that $\mathsf{ATR}_0$ proves the consistency of $\Sigma^1_1$-$\mathsf{DC}_0$ plus full induction. In chapter IX, we shall see that $\mathsf{RCA}_0$ and $\mathsf{WKL}_0$ prove the same $\Pi^1_1$ sentences, while $\mathsf{ACA}_0$ and $\Sigma^1_1$-$\mathsf{AC}_0$ prove the same $\Pi^1_2$ sentences.

## VIII.2. Countable Coded $\omega$-Models of $\mathsf{WKL}_0$

The formal system $\mathsf{WKL}_0$ was studied extensively in chapter IV. The purpose of this section is to present some results which imply the existence of a great many different countable $\omega$-models of $\mathsf{WKL}_0$. In particular we shall show that, although each such $\omega$-model contains nonrecursive sets, the only sets which are common to all such models are the recursive sets.

DEFINITION VIII.2.1 (strict $\beta$-submodels). $S\Sigma^1_1$ is the class of $\Sigma^1_1$ formulas of the form $\exists X\, \psi$ where $\psi$ is $\Pi^0_1$. ($S\Sigma^1_1$ stands for *strict* $\Sigma^1_1$.) We say that $M$ is a *strict $\beta$-submodel* of $M'$, written $M \subseteq_{S\beta} M'$, if $M \subseteq_\omega M'$ and, for all $S\Sigma^1_1$ sentences $\varphi$ with parameters from $M$, $M \models \varphi$ if and only if $M' \models \varphi$. (Compare definitions VII.1.11 and VII.2.28.)

THEOREM VIII.2.2. *Let $M'$ be a model of $\mathsf{WKL}_0$. For any $M \subseteq_\omega M'$, we have $M \subseteq_{S\beta} M'$ if and only if $M$ is a model of $\mathsf{WKL}_0$.*

PROOF. Assume first that $M \subseteq_{S\beta} M'$. In order to show that $M \models \mathsf{WKL}_0$, it suffices by lemma IV.4.4 to show that $M \models \Sigma^0_1$ separation. Let $\varphi(i,n)$ be a $\Sigma^0_1$ formula with parameters from $M$ and only the free variables shown, such that $\neg\exists n\,(\varphi(0,n) \wedge \varphi(1,n))$ holds. Since $M'$ is a model of $\mathsf{WKL}_0$, it follows that $M'$ satisfies

$$\exists X\, \forall n\, ((\varphi(1,n) \to n \in X) \wedge (\varphi(0,n) \to n \notin X)).$$

This assertion is strict $\Sigma^1_1$ and hence by assumption also true in $M$. This proves $\Sigma^0_1$ separation within $M$.

For the converse, assume that $M \subseteq_\omega M'$ is a model of $\mathsf{WKL}_0$. Let $\varphi$ be a strict $\Sigma^1_1$ sentence with parameters from $M$. Write $\varphi$ as $\exists X\, \psi(X)$ where $\psi(X)$ is $\Pi^0_1$. By the normal form theorem II.2.7, write $\psi(X)$ as $\forall m\, \theta(X[m])$ where $\theta$ is $\Sigma^0_0$. By $\Sigma^0_0$ comprehension within $M$, let $T$ be the set of $\tau \in 2^{<\mathbb{N}}$ such that $\forall m\, (m \leq \mathrm{lh}(\tau) \to \theta(\tau[m]))$. Thus $M \models T$ is a tree. Now if $M' \models \varphi$, we have $M' \models \exists X\, \psi(X)$, hence $M' \models \exists X\, \forall m\, \theta(X[m])$, hence $M' \models T$ is infinite. Since $M \subseteq_\omega M'$, it follows that $M \models T$ is infinite. Hence by weak König's lemma within $M$, we have $M \models \exists X\, (X$ is a path through $T)$, hence $M \models \exists X\, \forall m\, \theta(X[m])$, i.e., $\exists X\, \psi(X)$, i.e., $\varphi$. Thus $M \subseteq_{S\beta} M'$. This completes the proof. □

Our next goal is to show that $\mathsf{WKL}_0$ proves the existence of countable coded strict $\beta$-models (theorem VIII.2.6 below).

Definition VIII.2.3 (countable coded strict $\beta$-models). Within $\mathsf{RCA}_0$, let $\pi(e, m_1, X_1, X_2, X_3)$ be a universal lightface $\Pi^0_1$ formula with exactly the free variables shown. A *countable coded strict $\beta$-model* is a countable coded $\omega$-model $M$ such that, for all $e, m \in \mathbb{N}$ and $X, Y \in M$, $\exists Z\, \pi(e, m, X, Y, Z)$ if and only if $M \models \exists Z\, \pi(e, m, X, Y, Z)$.
(Compare definition VII.2.3.)

Lemma VIII.2.4.

1. *For any $\Pi^0_1$ formula $\psi(k, X)$, $\mathsf{WKL}_0$ proves*
$$\forall n\, \exists X\, (\forall k < n)\, \psi(k, X) \to \exists X\, \forall k\, \psi(k, X).$$
2. *For any $\Pi^0_1$ formula $\psi(X)$, we can find a $\Pi^0_1$ formula $\widehat{\psi}$ such that $\mathsf{WKL}_0$ proves $\widehat{\psi} \leftrightarrow \exists X\, \psi(X)$.*

Note that part 1 of this lemma amounts to a kind of *compactness principle* for $\Pi^0_1$ formulas in $\mathsf{WKL}_0$. Moreover, part 2 says any strict $\Sigma^1_1$ formula is equivalent over $\mathsf{WKL}_0$ to a $\Pi^0_1$ formula.

Proof. We first prove part 1. By the normal form theorem II.2.7, write $\psi(k, X)$ as $\forall m\, \theta(k, X[m])$ where $\theta$ is $\Sigma^0_0$. Let $T$ be the tree consisting of all $\tau \in 2^{<\mathbb{N}}$ such that $(\forall k \leq \mathrm{lh}(\tau))\, (\forall m \leq \mathrm{lh}(\tau))\, \theta(k, \tau[m])$. The assumption $\forall n\, \exists X\, (\forall k < n)\, \psi(k, X)$ implies that $\forall n\, \exists \tau\, (\mathrm{lh}(\tau) = n \wedge \tau \in T)$. Hence $T$ is infinite, so by weak König's lemma there exists a path $X$ through $T$. This implies $\forall k\, \psi(k, X)$. Part 1 is proved.

We now prove part 2. Write $\psi(X)$ as $\forall m\, \theta(X[m])$ where $\theta$ is $\Sigma^0_0$. Applying weak König's lemma as in the previous paragraph, we see that $\exists X\, \psi(X)$ is equivalent to the $\Pi^0_1$ formula $\widehat{\psi} \equiv \forall n\, \exists \tau\, (\mathrm{lh}(\tau) = n \wedge (\forall m \leq n)\, \theta(\tau[m]))$. This completes the proof of lemma VIII.2.4. □

Lemma VIII.2.5 (strong $\Pi^0_1$ dependent choice). $\mathsf{WKL}_0$ *proves the scheme of* strong $\Pi^0_1$ dependent choice:
$$\exists Z\, \forall n\, \forall Y\, (\eta(n, (Z)^n, Y) \to \eta(n, (Z)^n, (Z)_n))$$
*where $\eta(n, X, Y)$ is any $\Pi^0_1$ formula in which $Z$ does not occur.*
(Compare definition VII.6.1.4.)

Proof. By the normal form theorem II.2.7, write
$$\eta(n, X, Y) \equiv \forall k\, \theta(n, X, Y[k])$$
where $\theta$ is $\Sigma^0_0$. Define

$$\eta^+(n, X, Y) \equiv$$
$$\forall k\, \forall \tau\, ((\mathrm{lh}(\tau) = k \wedge (\forall i \leq k)\, \theta(n, X, \tau[i])) \to \theta(n, X, Y[k])).$$

By weak König's lemma, we have $\forall n\, \forall X\, \exists Y \eta^+(n, X, Y)$. By lemma VIII.2.4.2, let $\psi(n)$ be a $\Pi^0_1$ formula which is equivalent to

$\exists Z\,(\forall m < n)\,\eta^+(m,(Z)^m,(Z)_m)$. We have $\psi(0)$ and $\forall n\,(\psi(n) \to \psi(n+1))$, so by $\Pi^0_1$ induction (theorem II.3.10) it follows that $\forall n\,\psi(n)$ holds, i.e., $\forall n\,\exists Z\,(\forall m < n)\,\eta^+(m,(Z)^m,(Z)_m)$. Hence by compactness (lemma VIII.2.4.1), there exists $Z$ such that $\forall n\,\eta^+(n,(Z)^n,(Z)_n)$ holds. From this and the definition of $\eta^+$ it follows that $\forall n\,\forall Y\,(\eta(n,(Z)^n,Y) \to \eta(n,(Z)^n,(Z)_n))$. This proves the lemma. □

THEOREM VIII.2.6. *The following is provable in* $\mathsf{WKL}_0$. *For all* $X \subseteq \mathbb{N}$, *there exists a countable coded strict* $\beta$*-model* $M$ *such that* $X \in M$.

PROOF. Let $\pi(e,m_1,X_1,X_2,X_3)$ be a universal lightface $\Pi^0_1$ formula with exactly the free variables shown (definition VII.1.3). We reason within $\mathsf{WKL}_0$. Fix $X \subseteq \mathbb{N}$. By strong $\Pi^0_1$ dependent choice (lemma VIII.2.5), there exists $W$ such that

$$\forall n\,\forall e\,\forall m\,\forall Z\,((n=(e,m) \wedge \pi(e,m,X,(W)^n,Z)) \to \pi(e,m,X,(W)^n,(W)_n)).$$

It is straightforward to verify that $W$ is a code for a countable strict $\beta$-model $M$, and that $X \in M$. This completes the proof. (Compare the proof of theorem VII.7.4.) □

COROLLARY VIII.2.7 ($\omega$-submodels of $\mathsf{WKL}_0$). *Let* $M'$ *be any model of* $\mathsf{WKL}_0$. *Then for any* $X \in M'$ *there exists* $M \subseteq_\omega M'$ *such that* $M \neq M'$, $X \in M$, *and* $M$ *is again a model of* $\mathsf{WKL}_0$.

PROOF. Let $X \in M' \models \mathsf{WKL}_0$ be given. Applying theorem VIII.2.6 within $M'$, we get $W \in M'$ such that $M' \models (W$ is a code for a countable coded strict $\beta$-model $M$ such that $X \in M)$. In particular, it follows that $M \subseteq_{S\beta} M'$. Hence by theorem VIII.2.2 $M \models \mathsf{WKL}_0$. Also $M \neq M'$ since the set $Y = \{n\colon n \notin (W)_n\}$ belongs to $M'$ but not to $M$. This completes the proof. □

COROLLARY VIII.2.8. *There is no minimal* $\omega$*-model of* $\mathsf{WKL}_0$. *In other words, every* $\omega$*-model of* $\mathsf{WKL}_0$ *has another such model properly contained within it*.

The following consequence of the proof of theorem VIII.2.6 will be useful later in this section.

LEMMA VIII.2.9. *There is a* $\Pi^0_1$ *formula* $\psi(X,W)$ *such that*:

1. $\mathsf{WKL}_0$ *proves* $\forall X\,\exists W\,\psi(X,W)$;
2. $\mathsf{RCA}_0$ *proves* $\forall X\,\forall W\,(\psi(X,W) \to W$ *is a code of a countable coded strict* $\beta$*-model* $M$ *such that* $X \in M)$.

PROOF. As in the proof of theorem VIII.2.6, let $\pi(e,m_1,X_1,X_2,X_3)$ be universal lightface $\Pi^0_1$ with exactly the free variables shown. As in the proof of lemma VIII.2.5, write

$$\pi(e,m,X,Y,Z) \equiv \forall k\,\theta(e,m,X,Y,Z[k])$$

where $\theta$ is $\Sigma^0_0$, and define

$$\pi^+(e, m, X, Y, Z) \equiv$$
$$\forall k\, \forall \tau\, ((\mathrm{lh}(\tau) = k \wedge (\forall i \leq k)\, \theta(e, m, X, Y, \tau[i])) \rightarrow \theta(e, m, X, Y, Z[k])).$$

Then define $\psi(X, W)$ to be the $\Pi^0_1$ formula

$$\forall n\, \forall e\, \forall m\, (n = (e, m) \rightarrow \pi^+(e, m, X, (W)^n, (W)_n)).$$

As in the proof of lemma VIII.2.5, we can argue within $\mathsf{WKL}_0$ that

$$\forall X\, \exists W\, \psi(X, W).$$

This proves part 1. For part 2, note that $\psi(X, W)$ implies

$$\forall n\, \forall e\, \forall m\, \forall Z\, ((n = (e, m) \wedge \pi(e, m, X, (W)^n, Z)) \rightarrow \pi(e, m, X, (W)^n, (W)_n))$$

which, as in the proof of theorem VIII.2.6, implies that $W$ is a code for a countable strict $\beta$-model containing $X$. This completes the proof of lemma VIII.2.9. □

Next, we consider the relationship between $\mathsf{WKL}_0$ and $\mathsf{ACA}_0$.

Lemma VIII.2.10 (finite axiomatizability). $\mathsf{WKL}_0$ *is finitely axiomatizable.*

Proof. From §VIII.1 we know that $\mathsf{RCA}_0$ is finitely axiomatizable. The axioms of $\mathsf{WKL}_0$ can be taken to be those of $\mathsf{RCA}_0$ plus the single axiom $\forall T$ (if $T$ is an infinite subtree of $2^{<\mathbb{N}}$ then there exists a path through $T$). □

Theorem VIII.2.11. *The following is provable in* $\mathsf{ACA}_0$. *For all* $X \subseteq \mathbb{N}$, *there exists a countable* $\omega$*-model* $M$ *of* $\mathsf{WKL}_0$ *such that* $X \in M$.

Proof. We reason within $\mathsf{ACA}_0$. Fix $X \subseteq \mathbb{N}$. By theorem VIII.2.6 there exists a countable coded strict $\beta$-model $M$ such that $X \in M$. By lemma VIII.2.10 let $\varphi$ be the conjunction of the axioms of $\mathsf{WKL}_0$. Lemma VII.2.2 provides a valuation $f : \mathrm{Sub}_M(\varphi) \rightarrow \{0, 1\}$. We can then use the method of proof of theorem VIII.2.2 to verify that $f(\varphi) = 1$. This completes the proof. □

As in VIII.1.7 and VIII.1.8 we obtain the following corollaries.

Corollary VIII.2.12 (consistency of $\mathsf{WKL}_0$). $\mathsf{ACA}_0$ *proves the consistency of* $\mathsf{WKL}_0$.

Corollary VIII.2.13. *There exists a* $\Pi^0_1$ *sentence* $\psi$ *such that* $\psi$ *is provable in* $\mathsf{ACA}_0$ *but not in* $\mathsf{WKL}_0$.

Remark VIII.2.14. In connection with theorems VIII.2.6 and VIII.2.11, note that we have not claimed that $\mathsf{WKL}_0$ proves the existence of a countable coded $\omega$-model of $\mathsf{WKL}_0$. Indeed, Gödel's second incompleteness theorem [94, 115, 55, 222] shows that this cannot be the case.

The next lemma is implicit in what we have already done, but we now pause in order to make it explicit. Recall from definition VII.1.4 that $Y$ is *$X$-recursive* if and only if $Y \leq_T X$.

LEMMA VIII.2.15. *For any $X \subseteq \mathbb{N}$, there exists an $X$-recursive infinite tree $T \subseteq 2^{<\mathbb{N}}$ which has no $X$-recursive path. This is provable in* $\mathsf{RCA}_0$.

PROOF. Let $M'$ be any model of $\mathsf{RCA}_0$. Given $X \in M'$, let $M$ be the $\omega$-submodel of $M'$ consisting of all $Y \in M'$ such that $M' \models Y \leq_T X$. By theorem VIII.1.3 and corollary VIII.2.7, $M$ is a model of $\mathsf{RCA}_0$ but is not a model of $\mathsf{WKL}_0$. Hence there exists $T \in M$ such that $M \models (T$ is an infinite subtree of $2^{<\mathbb{N}}$ which has no path). Thus $M' \models (T$ is an infinite $X$-recursive subtree of $2^{<\mathbb{N}}$ which has no $X$-recursive path). This shows that our lemma is true in any model of $\mathsf{RCA}_0$. Hence, by the soundness theorem, our lemma is provable in $\mathsf{RCA}_0$. □

The results which we have presented so far in this section are of fundamental importance. The rest of the section is devoted to results which are of more specialized interest. We consider the so-called *basis problem*: Given an $X$-recursive infinite tree $T \subseteq 2^{<\mathbb{N}}$, to find a path $Y$ through $T$ such that $Y$ is in some sense "close to being $X$-recursive." Various solutions of the basis problem will be used to construct $\omega$-models of $\mathsf{WKL}_0$ with various properties.

A well known solution of the basis problem is given by the following lemma.

LEMMA VIII.2.16 (low basis theorem). *Let $X \subseteq \mathbb{N}$ be given, and let $T$ be any $X$-recursive infinite subtree of $2^{<\mathbb{N}}$. Then there exists a path $Y$ through $T$ such that* $\mathrm{TJ}(Y \oplus X) \leq_T \mathrm{TJ}(X)$. *This result is provable in* $\mathsf{ACA}_0$.

PROOF. As in the definition of Turing jump (definition VIII.1.9), let $\pi(e, m_1, X_1)$ be a universal lightface $\Pi^0_1$ formula. Fix $X \subseteq \mathbb{N}$ and define $\pi^*(n, X, Z) \equiv \forall e\, \forall m\, (n = (e, m) \to \pi(e, m, Z \oplus X))$. Thus for any $Z$ we have $\mathrm{TJ}(Z \oplus X) = \{n : \pi^*(n, X, Z)\}$. Let $G$ be the set of all $\sigma \in \mathbb{N}^{<\mathbb{N}}$ such that $\exists Z\, (\forall i < \mathrm{lh}(\sigma))\, \pi^*(\sigma(i), X, Z)$. By lemma VIII.2.4.2, the formula defining $G$ is equivalent to a $\Pi^0_1$ formula. Hence $G \leq_T \mathrm{TJ}(X)$. Let $n_0$ be such that $\forall Z\, (\pi^*(n_0, X, Z) \leftrightarrow Z$ is a path through $T)$. Define a sequence of finite sequences $\sigma_0 \subseteq \sigma_1 \subseteq \cdots \subseteq \sigma_n \subseteq \cdots$ by $\sigma_0 = \langle n_0 \rangle$, $\sigma_{n+1} = \sigma_n{}^\frown\langle n \rangle$ if $\sigma_n{}^\frown\langle n \rangle \in G$, otherwise $\sigma_{n+1} = \sigma_n$. Thus $\sigma_n \in G$ for all $n \in \mathbb{N}$, and the sequence $\langle \sigma_n : n \in \mathbb{N} \rangle$ is recursive in $G$. By compactness (lemma VIII.2.4.1), let $Y$ be such that $\pi^*(n_0, X, Y)$ and $\pi^*(n, X, Y)$ for all $n$ such that $\sigma_n{}^\frown\langle n \rangle \in G$. Thus $Y$ is a path through $T$ and, for all $n \in \mathbb{N}$, $n \in \mathrm{TJ}(Y \oplus X)$ if and only if $\sigma_n{}^\frown\langle n \rangle \in G$. Thus $\mathrm{TJ}(Y \oplus X) \leq_T G$. Since $G \leq_T \mathrm{TJ}(X)$ it follows that $\mathrm{TJ}(Y \oplus X) \leq_T \mathrm{TJ}(X)$. This completes the proof. □

THEOREM VIII.2.17. *For any $X \subseteq \mathbb{N}$, there exists a countable coded $\omega$-model $M$ of* $\mathsf{WKL}_0$ *such that $X \in M$ and, for all $Y \in M$,* $\mathrm{TJ}(Y \oplus X) \leq_T \mathrm{TJ}(X)$. *This result is provable in* $\mathsf{ACA}_0$.

Proof. Fix $X \subseteq \mathbb{N}$. Let $\psi(X, W)$ be a $\Pi^0_1$ formula as in lemma VIII.2.9. By lemma VIII.2.9 and the proof of theorem VIII.2.11, we have $\exists W\, \psi(X, W)$ and $\forall W\, (\psi(X, W) \to W$ is a code for a countable $\omega$-model of $\mathsf{WKL}_0$ which contains $X)$. By the normal form theorem II.2.7, write $\psi(X, W)$ as $\forall m\, \theta(X, W[m])$ where $\theta$ is $\Sigma^0_0$. Let $T$ be the tree of all $\tau \in 2^{<\mathbb{N}}$ such that $(\forall m \leq \mathrm{lh}(\tau))\, \theta(X, \tau[m])$. Thus $T$ is recursive in $X$ and $\forall W\, (\psi(X, W) \leftrightarrow W$ is a path through $T)$. Hence by lemma VIII.2.16 there exists $W$ such that $\psi(X, W)$ and $\mathrm{TJ}(W \oplus X) \leq_{\mathrm{T}} \mathrm{TJ}(X)$. Let $M$ be the countable $\omega$-model of $\mathsf{WKL}_0$ which is encoded by $W$. Then clearly $\mathrm{TJ}(Y \oplus X) \leq_{\mathrm{T}} \mathrm{TJ}(X)$ for all $Y \in M$. This completes the proof. □

Corollary VIII.2.18. *There exists an $\omega$-model $M$ of $\mathsf{WKL}_0$ such that every set $X \in M$ is low.*

(A set $X \subseteq \omega$ is said to be *low* if $\mathrm{TJ}(X) \leq_{\mathrm{T}} \mathrm{TJ}(\emptyset)$.)

A second solution of the basis problem is given by the following definition and lemma. Recall that $g : \mathbb{N} \to \mathbb{N}$ is said to be *majorized* by $f : \mathbb{N} \to \mathbb{N}$ if $f(m) \geq g(m)$ for all $m \in \mathbb{N}$.

Definition VIII.2.19. For $X, Y \subseteq \mathbb{N}$, we say that $Y$ is *almost $X$-recursive* if for every $Y \oplus X$-recursive function $g : \mathbb{N} \to \mathbb{N}$ there exists an $X$-recursive function $f : \mathbb{N} \to \mathbb{N}$ such that $f$ majorizes $g$. This definition is made in $\mathsf{RCA}_0$.

Lemma VIII.2.20 (almost recursive basis theorem). *Let $X \subseteq \mathbb{N}$ be given. For any infinite $X$-recursive tree $T \subseteq 2^{<\mathbb{N}}$, there exists an almost $X$-recursive path $Y$ through $T$. This result is provable in $\mathsf{ACA}_0$.*

Proof. The proof is similar to that of lemma VIII.2.16. Let $\pi(e, m_1, m_2, X_1, X_2)$ be a universal lightface $\Pi^0_1$ formula with exactly the displayed free variables (definition VII.1.3). Let $G$ be the set of all finite sequences of pairs

$$\langle (e_0, m_0), (e_1, m_1), \ldots, (e_k, m_k) \rangle$$

such that $\exists Z\, (\forall i \leq k)\, \forall n\, \pi(e_i, m_i, n, X, Z)$. Define an infinite sequence of finite sequences $\sigma_0 \subseteq \sigma_1 \subseteq \cdots \subseteq \sigma_e \subseteq \cdots$ in $G$ as follows. Begin with $\sigma_0 = \langle (e'_0, m'_0) \rangle$ where $e'_0$ and $m'_0$ are chosen so that

$$\forall Z\, \forall n\, (\pi(e'_0, m'_0, n, X, Z) \leftrightarrow Z \text{ is a path through } T).$$

Since $T$ has a path, $\sigma_0 \in G$. Given $\sigma_e \in G$, if there exists $m$ such that $\sigma_e{}^\frown \langle (e, m) \rangle \in G$, let $m'_e$ be the least such $m$ and put $\sigma_{e+1} = \sigma_e{}^\frown \langle (e, m'_e) \rangle$. Otherwise put $m'_e = 0$ and $\sigma_{e+1} = \sigma_e$. Finally by compactness (lemma VIII.2.4.1) let $Y$ be such that $\forall n\, \pi(e'_0, m'_0, n, X, Y)$ and $\forall n\, \pi(e, m'_e, n, X, Y)$ hold for all $e$ such that $\sigma_{e+1} = \sigma_e{}^\frown \langle (e, m'_e) \rangle$. In particular $Y$ is a path through $T$.

We claim that $Y$ is almost $X$-recursive. To see this, let $g : \mathbb{N} \to \mathbb{N}$ be $Y \oplus X$-recursive. The graph of $g$ is $\Sigma^0_1$ in $Y \oplus X$ so let $e$ be such that

$$\forall m\, \forall n\, (g(m) = n \leftrightarrow \neg \pi(e, m, n, X, Y)).$$

In particular we have $\neg\pi(e, m_e, g(m_e), X, Y)$, hence $m'_e = 0$ and $\sigma_e{}^\frown\langle(e, m'_e)\rangle \notin G$. Write

$$\psi(X, Z) \equiv (\forall i \leq k)\, \forall n\, \pi(e_i, m_i, n, X, Z)$$

where $\sigma_e = \langle(e_0, m_0), (e_1, m_1), \ldots, (e_k, m_k)\rangle$. Thus $\psi(X, Z)$ is $\Pi^0_1$ and we have $\psi(X, Y)$ and

$$\forall m\, \forall Z\, (\psi(X, Z) \to \exists n\, \neg\pi(e, m, n, X, Z)).$$

Hence by compactness (lemma VIII.2.4.1), it follows that

$$\forall m\, \exists j\, \forall Z\, (\psi(X, Z) \to (\exists n \leq j) \neg\pi(e, m, n, X, Z)).$$

By lemma VIII.2.4.2 the subformula

$$\forall Z\, (\psi(X, Z) \to (\exists n \leq j)\, \neg\pi(e, m, n, X, Z))$$

is equivalent to a $\Sigma^0_1$ formula, say $\exists i\, \theta(i, j, m, X)$ where $\theta$ is $\Sigma^0_0$. We have $\forall m\, \exists i\, \exists j\, \theta(i, j, m, X)$ so define $f : \mathbb{N} \to \mathbb{N}$ by putting $f(m) =$ least $(i, j)$ such that $\theta(i, j, m, X)$. Then $f$ is $X$-recursive and we have

$$\forall m\, \forall Z\, (\psi(X, Z) \to (\exists n \leq f(m))\, \neg\pi(e, m, n, X, Z)).$$

In particular $\forall m\, (\exists n \leq f(m))\, \neg\pi(e, m, n, X, Y)$, in other words

$$\forall m\, g(m) \leq f(m).$$

This completes the proof. □

THEOREM VIII.2.21. *For any $X \subseteq \mathbb{N}$, there exists a countable coded $\omega$-model $M$ of $\mathsf{WKL}_0$ such that $X \in M$ and, for all $Y \in M$, $Y$ is almost $X$-recursive. This result is provable in $\mathsf{ACA}_0$.*

PROOF. This follows from lemma VIII.2.20 just as theorem VIII.2.17 followed from lemma VIII.2.16. □

COROLLARY VIII.2.22. *There exists an $\omega$-model $M$ of $\mathsf{WKL}_0$ such that, for all $X \in M$, $X$ is almost recursive.*

(A set $X \subseteq \omega$ is said to be *almost recursive* if every $X$-recursive function $g : \omega \to \omega$ is majorized by some recursive function $f : \omega \to \omega$.)

A third solution of the basis problem is given by the following lemma. Recall that, for $Y \subseteq \mathbb{N}$ and $j \in \mathbb{N}$,

$$(Y)_j = \{m : (m, j) \in Y\}.$$

LEMMA VIII.2.23 (GKT basis theorem). *Let $X \subseteq \mathbb{N}$ and $\langle A_i : i \in \mathbb{N}\rangle$, $A_i \subseteq \mathbb{N}$ be given such that $\forall i\, A_i \not\leq_{\mathrm{T}} X$. For any infinite $X$-recursive tree $T \subseteq 2^{<\mathbb{N}}$, there exists a path $Y$ through $T$ such that $\forall i\, \forall j\, A_i \neq (Y)_j$. This result is provable in $\mathsf{ACA}_0$.*

(Compare lemma VIII.6.4.)

PROOF. The proof is similar to that of lemma VIII.2.20. As usual, we shall identify $Z \subseteq \mathbb{N}$ with $Z\colon \mathbb{N} \to \{0,1\}$, $Z(n) = 1$ if $n \in Z$, 0 otherwise. We define an infinite sequence of triples $(\varepsilon_k, m_k, j_k)$, $k \in \mathbb{N}$, as follows. Begin by putting $m_0 = j_0 = 0$ and $\varepsilon_0 = (Z)_0(0)$ where $Z$ is some path through $T$. Now assume inductively that $(\varepsilon_0, m_0, j_0), \ldots, (\varepsilon_k, m_k, j_k)$ have already been defined so that $\exists Z\, \psi_k(X, Z)$ holds, where $\psi_k(X, Z)$ is the $\Pi^0_1$ formula

$$(Z \text{ is a path through } T) \wedge (\forall i \leq k)\,((Z)_{j_i}(m_i) = \varepsilon_i).$$

We shall now define $(\varepsilon_{k+1}, m_{k+1}, j_{k+1})$. If $k \notin \mathbb{N} \times \mathbb{N}$, put

$$(\varepsilon_{k+1}, m_{k+1}, j_{k+1}) = (\varepsilon_k, m_k, j_k).$$

Otherwise, put $k = (i, j)$. We claim that there exists $m$ such that

$$\exists Z\,(\psi_k(X, Z) \wedge A_i(m) \neq (Z)_j(m)).$$

If this were not so, we would have

$$\forall m\,(m \in A_i \leftrightarrow \exists Z\,(\psi_k(X, Z) \wedge m \in (Z)_j))$$

and

$$\forall m\,(m \in A_i \leftrightarrow \forall Z\,(\psi_k(X, Z) \rightarrow m \in (Z)_j))$$

which by lemma VIII.2.4.2 would imply that $A_i$ is $\Delta^0_1$ definable from $X$, i.e., $A_i \leq_{\mathrm{T}} X$, a contradiction. This proves the claim, so let $m_{k+1}$ be the least $m$ such that $\exists Z\,(\psi_k(X, Z) \wedge A_i(m) \neq (Z)_j(m))$, and put $j_{k+1} = j$ and $\varepsilon_{k+1} = 1 - A_i(m_{k+1})$. This completes the definition of $(\varepsilon_k, m_k, j_k)$ for all $k$. Now by compactness (lemma VIII.2.4.1), let $Y$ be a path through $T$ such that $\forall k\,(Y)_{j_k}(m_k) = \varepsilon_k$. This implies $\forall i\,\forall j\,\exists m\,(Y)_j(m) \neq A_i(m)$ and the proof is complete. □

THEOREM VIII.2.24. *Let $X \subseteq \mathbb{N}$ and $\langle A_i : i \in \mathbb{N}\rangle$, $A_i \subseteq \mathbb{N}$ be given such that $\forall i\ A_i \not\leq_{\mathrm{T}} X$. Then there exists a countable coded $\omega$-model $M$ of $\mathsf{WKL}_0$ such that $X \in M$ and $\forall i\ A_i \notin M$. This result is provable in $\mathsf{ACA}_0$.*

PROOF. This follows from lemma VIII.2.23 just as theorem VIII.2.17 followed from lemma VIII.2.16. □

COROLLARY VIII.2.25. *Given countably many nonrecursive sets $A_i$, $i \in \omega$, there exists a countable $\omega$-model $M$ of $\mathsf{WKL}_0$ such that $\forall i\ A_i \notin M$.*

COROLLARY VIII.2.26. *For any countable $\omega$-model $M_1$ of $\mathsf{RCA}_0$, there exists a countable $\omega$-model $M_2$ of $\mathsf{WKL}_0$ such that $M_1 \cap M_2 = \mathrm{REC}$, where $\mathrm{REC} = \{X : X \text{ is recursive}\}$.*

PROOF. Let $A_i$, $i \in \omega$, be an enumeration of the nonrecursive sets in $M_1$ and apply corollary VIII.2.25. □

COROLLARY VIII.2.27. REC *is the intersection of all $\omega$-models of $\mathsf{WKL}_0$.*

**Notes for §VIII.2.** Scott [217] has characterized countable $\omega$-models of $\mathsf{WKL}_0$ in the following way: $M$ is a countable $\omega$-model of $\mathsf{WKL}_0$ if and only if there exists a complete extension $T$ of PA such that for all $X \subseteq \mathbb{N}$, $X \in M$ if and only if $X$ is representable in $T$. Such $\omega$-models are sometimes known as *Scott systems*. Corollary VIII.2.7 is essentially due to Scott/Tennenbaum [218]; see also Jockusch/Soare [134]. Our lemma VIII.2.5 on strong $\Pi^0_1$ dependent choice appears to be new.

Theorem VIII.2.11 and lemma VIII.2.15 are well known, but their origins seem difficult to trace. See the references in Shoenfield [220], e.g., Kleene [142, §72]. According to Kleene [145, note 1], the use of the term "basis" is due to Kreisel. The GKT basis theorem VIII.2.23 is from Gandy/Kreisel/Tait [89]. The low and almost recursive basis theorems VIII.2.16 and VIII.2.20 are from Jockusch/Soare [134].

## VIII.3. Hyperarithmetical Sets

In this section we shall develop a technical tool, *relative hyperarithmeticity*, which will be used later in the chapter to study $\omega$-models of $\Delta^1_1$-$\mathsf{CA}_0$, $\mathsf{ATR}_0$, and stronger systems.

For $X, Y \subseteq \mathbb{N}$, we shall say that $Y$ *is hyperarithmetical in* $X$, abbreviated $Y \leq_{\mathrm{H}} X$, if $Y$ can be obtained by starting with $X$ and iterating the Turing jump operator along an $X$-recursive well ordering. (The details are in definitions VIII.3.5 and VIII.3.16 below.) We shall see that the principal axiom of $\mathsf{ATR}_0$ is equivalent to the assertion that these iterations can be carried out (theorem VIII.3.15). The main theorem of this section is that $Y$ is hyperarithmetical in $X$ if and only if $Y$ is $\Delta^1_1$ in $X$ (theorem VIII.3.19). At the end of the section, we shall use the method of pseudohierarchies (previously introduced in §V.4) to prove an important theorem about hyperarithmetical quantifiers.

The next three definitions are made in $\mathsf{RCA}_0$.

DEFINITION VIII.3.1. An $X$-*recursive linear ordering* is a countable linear ordering (definition V.1.1) which is $X$-recursive (definition VII.1.4). The $X$-recursive linear ordering with $X$-recursive index $e$ is denoted $\leq^X_e$.

DEFINITION VIII.3.2. Fix $X \subseteq \mathbb{N}$. We write $\mathcal{O}_+(a, X)$ to mean that $a = (e, i)$ for some $e$ and $i$ such that $e$ is an $X$-recursive index of an $X$-recursive linear ordering $\leq^X_e$ and $i \in \mathrm{field}(\leq^X_e)$. The set of all $a$ such that $\mathcal{O}_+(a, X)$ holds is denoted $\mathcal{O}^X_+$ if it exists. (For instance, the existence of $\mathcal{O}^X_+$ for all $X$ is provable in $\mathsf{ACA}_0$.) If $\mathcal{O}_+(a, X)$ and $\mathcal{O}_+(b, X)$, we write $b \leq^X_{\mathcal{O}} a$ (respectively $b <^X_{\mathcal{O}} a$) to mean that $a = (e, i)$ and $b = (e, j)$ for some $e, i$ and $j$ such that $j \leq^X_e i$ (respectively $j <^X_e i$). Note that $\leq^X_{\mathcal{O}}$ linearly orders $\{b : b <^X_{\mathcal{O}} a\}$ for each $a$ such that $\mathcal{O}_+(a, X)$ holds.

DEFINITION VIII.3.3 (ordinal notations). Fix $X \subseteq \mathbb{N}$. We write $\mathcal{O}(a, X)$ to mean that $\mathcal{O}_+(a, X)$ and there is no infinite descending sequence $\langle a_n : n \in \mathbb{N}\rangle$, $a = a_0 >_{\mathcal{O}}^X a_1 >_{\mathcal{O}}^X \cdots >_{\mathcal{O}}^X a_n >_{\mathcal{O}}^X \cdots$. The set of all $a$ such that $\mathcal{O}(a, X)$ holds is denoted $\mathcal{O}^X$ if it exists. (For instance, the existence of $\mathcal{O}^X$ for all $X$ is provable in $\Pi^1_1$-$\mathsf{CA}_0$.) Note that $\leq_{\mathcal{O}}^X$ well orders $\{b : b <_{\mathcal{O}}^X a\}$ for each $a$ such that $\mathcal{O}(a, X)$ holds.

The ideas underlying the above definitions are as follows. Suppose that $a \in \mathcal{O}_+^X$ where $a = (e, i)$. Then we think of $e$ as being an $X$-recursive *system of ordinal notations*, and we think of $i$ as being one of the notations in the system. If in addition $a \in \mathcal{O}^X$, then this means that the system of notations $e$ is well ordered up to and including the notation $i$. The ordinal of which $i$ is a notation is then the order type of $\{j : j <_e^X i\}$ under $\leq_e^X$, i.e., the order type of $\{b : b <_{\mathcal{O}}^X a\}$ under $\leq_{\mathcal{O}}^X$. This ordinal might be written as $|i|_e^X$ or more simply $|a|^X$. The least ordinal not expressible as $|a|^X$ for some $a \in \mathcal{O}^X$ is sometimes denoted $\omega_1^X$. In particular $\omega_1^{\mathrm{CK}} = \omega_1^{\emptyset}$.

The following lemma is a refinement of theorem V.1.9. It says in effect that, for any fixed $X \subseteq \mathbb{N}$, $\mathcal{O}^X$ is not $\Sigma^1_1$ definable from $X$.

LEMMA VIII.3.4. *Let $\varphi(n, X)$ be any $\Sigma^1_1$ formula with no free set variables other than $X$. Then* $\mathsf{ACA}_0$ *proves*

$$\neg\forall a\, (\varphi(a, X) \leftrightarrow \mathcal{O}(a, X)).$$

PROOF. We reason in $\mathsf{ACA}_0$. Fix $X$ and put

$$\psi(m, X) \equiv \forall f\, \neg\pi(m, m, X, f)$$

where $\pi(e, m_1, X_1, X_2)$ is universal lightface $\Pi^0_1$ as in the definition of the hyperjump (definition VII.1.5). Note that $\psi(m, X)$ is a $\Pi^1_1$ formula obtained by diagonalization.

By the Kleene normal form theorem II.2.7, let $\theta(m, \sigma, \tau)$ be a $\Sigma^0_0$ formula such that $\forall m\, (\pi(m, m, X, f) \leftrightarrow \forall k\, \theta(m, X[k], f[k]))$. For each $m \in \mathbb{N}$ we have an $X$-recursive tree

$$T_m^X = \{\tau \in \mathbb{N}^{<\mathbb{N}} : (\forall k \leq \mathrm{lh}(\tau))\, \theta(m, X[k], \tau[k])\}.$$

Let $R_m^X = \mathrm{KB}(T_m^X)$ be the Kleene/Brouwer ordering of $T_m^X$. Then for all $m \in \mathbb{N}$, $R_m^X$ is an $X$-recursive linear ordering, and we have

$$\begin{aligned}
\psi(m, X) &\leftrightarrow \forall f\, \neg\pi(m, m, X, f) \\
&\leftrightarrow \forall f\, \exists k\, \neg\theta(m, X[k], f[k]) \\
&\leftrightarrow T_m^X \text{ has no path} \\
&\leftrightarrow R_m^X \text{ is a well ordering.}
\end{aligned}$$

Suppose now that $\forall a\,(\varphi(a,X) \leftrightarrow \mathcal{O}(a,X))$ where $\varphi(a,X)$ is $\Sigma^1_1$ with no free set variables other than $X$. Then for all $m \in \mathbb{N}$ we have

$$\begin{aligned}\psi(m,X) &\leftrightarrow R^X_m \text{ is a well ordering}\\ &\leftrightarrow \exists a\,(\varphi(a,X) \wedge \exists \text{ isomorphism of } R^X_m \text{ onto } \{b\colon b <^X_{\mathcal{O}} a\}).\end{aligned}$$

This is $\Sigma^1_1$ so, as in the proof of lemma VII.1.6, we have

$$\exists e\,\forall m\,(\psi(m,X) \leftrightarrow \exists f\,\pi(e,m,X,f)).$$

For this particular $e$, $\psi(e,X)$ is equivalent to $\exists f\,\pi(e,e,X,f)$, which is equivalent to $\neg\psi(e,X)$, a contradiction. This proves lemma VIII.3.4. □

We now present the key definition of this section.

DEFINITION VIII.3.5 (H-sets). The following definition is made in $\mathsf{ATR}_0$. Fix $X \subseteq \mathbb{N}$. For each $a$ such that $\mathcal{O}(a,X)$ holds, we define a set $\mathrm{H}^X_a \subseteq \mathbb{N}$ by

$$\mathrm{H}^X_a = \{(m,0)\colon m \in X\} \cup \{(m,b+1)\colon b <^X_{\mathcal{O}} a \wedge m \in \mathrm{TJ}(\mathrm{H}^X_b)\}.$$

Here TJ denotes the Turing jump operator (definition VIII.1.9).

The sets $\mathrm{H}^X_a$ where $\mathcal{O}(a,X)$ holds are known as H-*sets*. The idea behind the H-sets is that $\mathrm{H}^X_a$ is the result of iterating the Turing jump operator along the $X$-recursive well ordering $\{b\colon b <^X_{\mathcal{O}} a\}$ starting with $X$. (See lemmas VIII.3.9, VIII.3.10 and VIII.3.13 below.) The existence and uniqueness of $\mathrm{H}^X_a$ are assured by arithmetical transfinite recursion and arithmetical transfinite induction, respectively. (See §V.2.)

We shall sometimes want to consider H-sets in situations where the full strength of arithmetical transfinite recursion is not available. We therefore generalize the concept of H-set as follows.

DEFINITION VIII.3.6. The following definition is made in $\mathsf{ACA}_0$. Recall the notation $(Y)_k = \{m\colon (m,k) \in Y\}$. Let $\mathrm{H}(a,X,Y)$ be the arithmetical formula

$$\begin{aligned}&\mathcal{O}_+(a,X)\\ &\wedge\ Y = \{(m,0)\colon m \in X\} \cup \{(m,b+1)\colon b <^X_{\mathcal{O}} a \wedge m \in (Y)_{b+1}\}\\ &\wedge\ \forall b(b <^X_{\mathcal{O}} a \to (Y)_{b+1} = \mathrm{TJ}(\{m,0)\colon m \in X\}\\ &\qquad\qquad \cup \{(m,c+1)\colon c <^X_{\mathcal{O}} b \wedge m \in (Y)_{c+1}\})).\end{aligned}$$

Intuitively, $\mathrm{H}(a,X,Y)$ means that $\mathcal{O}_+(a,X)$ holds and that $Y$ "looks like" $\mathrm{H}^X_a$ although $\mathcal{O}(a,X)$ is not assumed.

LEMMA VIII.3.7. *The following is provable in* $\mathsf{ACA}_0$. *If* $\mathcal{O}(a,X)$ *holds, then there is at most one* $Y$ *such that* $\mathrm{H}(a,X,Y)$ *holds.*

(Compare lemma V.2.3.)

PROOF. This is a special case of lemma V.2.3. The proof is immediate by arithmetical transfinite induction (lemma V.2.1). □

DEFINITION VIII.3.8 (existence of $\mathrm{H}_a^X$). This definition is made in $\mathsf{ACA}_0$. Assume that $\mathcal{O}(a, X)$ holds. We write $\mathrm{H}_a^X$ *exists* to mean that $\exists Y\, \mathrm{H}(a, X, Y)$, in which case we put $\mathrm{H}_a^X =$ the unique $Y$ such that $\mathrm{H}(a, X, Y)$. (Lemma VIII.3.7 tells us that $\mathrm{H}_a^X$ is unique if it exists.)

LEMMA VIII.3.9. *The following is provable in* $\mathsf{ACA}_0$. *Assume that* $\mathcal{O}(a, X)$ *holds.*

1. *If* $\mathrm{H}_a^X$ *exists and* $b <_{\mathcal{O}}^X a$, *then* $\mathrm{H}_b^X$ *exists and is* $<_{\mathrm{T}} \mathrm{H}_a^X$.
2. *Suppose that* $|a|^X = 0$, *i.e., there is no* $b$ *such that* $b <_{\mathcal{O}}^X a$. *Then* $\mathrm{H}_a^X$ *exists and* $\mathrm{H}_a^X =_{\mathrm{T}} X$.
3. *Suppose that* $b <_{\mathcal{O}}^X a$ *and* $|a|^X = |b|^X + 1$, i..e., *there is no* $c$ *such that* $b <_{\mathcal{O}}^X c <_{\mathcal{O}}^X a$. *Then* $\mathrm{H}_a^X$ *exists if and only if* $\mathrm{H}_b^X$ *exists, in which case* $\mathrm{H}_a^X =_{\mathrm{T}} \mathrm{TJ}(\mathrm{H}_b^X)$.

PROOF. If $b <_{\mathcal{O}}^X a$, then $\mathrm{TJ}(\mathrm{H}_b^X) = (\mathrm{H}_a^X)_{b+1}$, hence $\mathrm{H}_b^X <_{\mathrm{T}} \mathrm{TJ}(\mathrm{H}_b^X) \leq_{\mathrm{T}} \mathrm{H}_a^X$. If $|a|^X = 0$, we have $\mathrm{H}_a^X = \{(m, 0) \colon m \in X\}$ and obviously this is $=_{\mathrm{T}} X$. Suppose now that $b <_{\mathcal{O}}^X a$ and $|a|^X = |b|^X + 1$. In this case, the desired conclusions follow easily from the identities $\mathrm{TJ}(\mathrm{H}_b^X) = (\mathrm{H}_a^X)_{b+1}$ and

$$\mathrm{H}_a^X = \mathrm{H}_b^X \cup \{(m, b+1) \colon m \in \mathrm{TJ}(\mathrm{H}_b^X)\}.$$

This completes the proof of lemma VIII.3.9. □

LEMMA VIII.3.10. *Assume that* $\mathcal{O}(a, X)$ *holds and that* $\mathrm{H}_a^X$ *exists. Suppose that* $|a|^X$ *is a limit ordinal, i.e.,* VIII.3.9.2 *and* VIII.3.9.3 *do not apply. For any arithmetical formula* $\psi(m, X)$ *with exactly the free variables shown, it is provable in* $\mathsf{ACA}_0$ *that the set*

$$\{(m, b) \colon b <_{\mathcal{O}}^X a \wedge \psi(m, \mathrm{H}_b^X)\}$$

*exists and is* $\leq_{\mathrm{T}} \mathrm{H}_a^X$.

In order to prove lemma VIII.3.10, we first prove the following sublemmas.

SUBLEMMA VIII.3.11. *Let* $\psi(m, Y)$ *be an arithmetical formula with no free set variables other than* $Y$. *Then we can find* $k < \omega$ *such that* $\mathsf{ACA}_0$ *proves*

$$\exists e\, \forall m\, \forall Y\, (\psi(m, Y) \leftrightarrow (m, e) \in \mathrm{TJ}(k, Y)).$$

PROOF. We shall in fact show that $k$ may be taken to be such that $\psi(m, Y)$ is a $\Pi_k^0$ formula. Assume first that $k = 1$, i.e., $\psi(m, Y)$ is $\Pi_1^0$. Let $\pi(e, m_1, X_1)$ be the universal lightface $\Pi_1^0$ formula with exactly the free variables shown, as in the definition of Turing jump (definition VIII.1.9). Thus $\mathsf{ACA}_0$ (in fact $\mathsf{RCA}_0$) proves $\exists e\, \forall m\, \forall Y\, (\psi(m, Y) \leftrightarrow \pi(e, m, Y))$. For this $e$ we have $\forall m\, (\psi(m, Y) \leftrightarrow (m, e) \in \mathrm{TJ}(Y))$ so the sublemma is proved in this case. Assume now that $\psi(m, Y)$ is $\Pi_k^0$, $1 < k < \omega$. Write $\psi(m, Y) \equiv \forall n\, \varphi(m, n, Y)$ where $\varphi(m, n, Y)$ is $\Sigma_{k-1}^0$. Then $\neg\varphi(m, n, Y)$ is $\Pi_{k-1}^0$ so by induction on $k$ we have that $\mathsf{ACA}_0$ proves

$\exists e' \forall m \forall n \forall Y (\neg\varphi(m, n, Y) \leftrightarrow ((m, n), e') \in \mathrm{TJ}(k-1, Y))$. Note also that $\mathsf{ACA}_0$ (in fact $\mathsf{RCA}_0$) proves

$$\forall e' \exists e \forall m \forall Y (\pi(e, m, Y) \leftrightarrow \forall n ((m, n), e') \notin Y).$$

Thus, reasoning in $\mathsf{ACA}_0$, we have

$$\begin{aligned}\psi(m, Y) &\leftrightarrow \forall n \varphi(m, n, Y)\\ &\leftrightarrow \forall n ((m, n), e') \notin \mathrm{TJ}(k-1, Y)\\ &\leftrightarrow \pi(e, m, TJ(k-1, Y))\\ &\leftrightarrow (m, e) \in \mathrm{TJ}(k, Y).\end{aligned}$$

This completes the proof of sublemma VIII.3.11. □

SUBLEMMA VIII.3.12. *The following is provable in* $\mathsf{ACA}_0$. *There is a fixed integer* $i_0 \in \mathbb{N}$ *such that, for all* $Y \subseteq \mathbb{N}$ *and all* $k \in \mathbb{N}$,

$$\mathrm{TJ}((Y)_k) = ((\mathrm{TJ}(Y))_{i_0})_k.$$

PROOF. Let $\pi(e, m_1, X_1)$ be a universal lightface $\Pi^0_1$ formula as in the definition of Turing jump (definition VIII.1.9). Since the formula $m \in \mathrm{TJ}((Y)_k)$ is $\Pi^0_1$, we can prove within $\mathsf{ACA}_0$ (in fact within $\mathsf{RCA}_0$) the existence of an integer $e$ such that $\pi(e, (m, k), Y) \leftrightarrow m \in \mathrm{TJ}((Y)_k)$ holds for all $Y \subseteq \mathbb{N}$ and $k, m \in \mathbb{N}$. Letting $i_0$ be any such $e$, we have for all $Y$, $k$ and $m$

$$\begin{aligned}m \in \mathrm{TJ}((Y)_k) &\leftrightarrow \pi(i_0, (m, k), Y)\\ &\leftrightarrow ((m, k), i_0) \in \mathrm{TJ}(Y)\\ &\leftrightarrow (m, k) \in (TJ(Y))_{i_0}\\ &\leftrightarrow m \in ((\mathrm{TJ}(Y))_{i_0})_k.\end{aligned}$$

Hence $\mathrm{TJ}((Y)_k) = ((\mathrm{TJ}(Y)_{i_0})_k$ and the sublemma is proved. □

PROOF OF LEMMA VIII.3.10. Let $\psi(m, Y)$ be arithmetical with no free set variables other than $Y$. By sublemma VIII.3.11, let $k < \omega$ be such that $\mathsf{ACA}_0$ proves $\exists e \forall m \forall Y (\psi(m, Y) \leftrightarrow (m, e) \in \mathrm{TJ}(k, Y))$. Reasoning in $\mathsf{ACA}_0$, assume that $\mathcal{O}(a, X)$ holds, that $|a|^X$ is a limit ordinal, and that $\mathrm{H}^X_a$ exists. Let

$$' : \{b : b <^X_{\mathcal{O}} a\} \to \{b : b <^X_{\mathcal{O}} a\}$$

be such that $|b'|^X = |b|^X + 1$ for all $b <^X_{\mathcal{O}} a$. The function $'$ is clearly $\leq_{\mathrm{T}} \mathrm{TJ}(X)$ and hence $\leq_{\mathrm{T}} \mathrm{H}^X_a$. For each $b <^X_{\mathcal{O}} a$, we have $b <^X_{\mathcal{O}} b' <^X_{\mathcal{O}} a$,

hence

$$\begin{aligned}
\mathrm{TJ}(\mathrm{H}_b^X) &= (\mathrm{H}_{b'}^X)_{b+1} = (\mathrm{H}_a^X)_{b+1};\\
\mathrm{TJ}(2, \mathrm{H}_b^X) &= \mathrm{TJ}(\mathrm{TJ}(\mathrm{H}_b^X)) = \mathrm{TJ}((\mathrm{H}_{b'}^X)_{b+1}) = ((\mathrm{TJ}(\mathrm{H}_{b'}^X))_{i_0})_{b+1}\\
&= (((\mathrm{H}_{b''}^X)_{b'+1})_{i_0})_{b+1} = (((\mathrm{H}_a^X)_{b'+1})_{i_0})_{b+1};\\
\mathrm{TJ}(3, \mathrm{H}_b^X) &= \mathrm{TJ}(\mathrm{TJ}(2, \mathrm{H}_b^X)) = \mathrm{TJ}((((\mathrm{H}_{b''}^X)_{b'+1})_{i_0})_{b+1})\\
&= ((((((\mathrm{TJ}(\mathrm{H}_{b''}^X))_{i_0})_{b'+1})_{i_0})_{i_0})_{b+1}\\
&= (((((((\mathrm{H}_{b'''}^X)_{b''+1})_{i_0})_{b'+1})_{i_0})_{i_0})_{b+1}\\
&= (((((((\mathrm{H}_a^X)_{b''+1})_{i_0})_{b'+1})_{i_0})_{i_0})_{b+1};\\
\mathrm{TJ}(4, \mathrm{H}_b^X) &= \mathrm{TJ}(\mathrm{TJ}(3, \mathrm{H}_b^X)) = \cdots;
\end{aligned}$$

etc., where $i_0$ is as in sublemma VIII.3.12. If for instance $k = 2$, then for an appropriate $e$ and all $b <_{\mathcal{O}}^X a$ and all $m$, we have

$$\begin{aligned}
\psi(m, \mathrm{H}_b^X) &\leftrightarrow (m, e) \in \mathrm{TJ}(2, \mathrm{H}_b^X)\\
&\leftrightarrow (m, e) \in (((\mathrm{H}_a^X)_{b'+1})_{i_0})_{b+1}
\end{aligned}$$

from which it follows immediately that

$$\{(m, b) : b <_{\mathcal{O}}^X a \wedge \psi(m, \mathrm{H}_b^X)\}$$

is recursive in $\mathrm{H}_a^X$. This proves lemma VIII.3.10. □

The next lemma implies that the Turing degree of $\mathrm{H}_a^X$ depends only on the ordinal $|a|^X$. Thus, for every ordinal $\alpha < \omega_1^X$, we may define the $\alpha$th Turing jump of $X$ by putting $\mathrm{TJ}(\alpha, X) = \mathrm{H}_a^X$ for some $a \in \mathcal{O}^X$ with $|a|^X = \alpha$, and this is well defined up to Turing degree.

LEMMA VIII.3.13. *The following is provable in* $\mathsf{ACA}_0$. *Suppose that* $\mathcal{O}(a, X)$ *and* $\mathcal{O}(a^*, X)$. *Assume that* $|a|^X = |a^*|^X$, *i.e., there exists an order isomorphism of* $\{b : b <_{\mathcal{O}}^X a\}$ *onto* $\{c : c <_{\mathcal{O}}^X a^*\}$. *If* $\mathrm{H}_a^X$ *exists, then* $\mathrm{H}_{a^*}^X$ *exists and is* $=_{\mathrm{T}} \mathrm{H}_a^X$.

PROOF. Assume that $\mathrm{H}_a^X$ exists. We want to show that $\mathrm{H}_{a^*}^X$ exists and is $=_{\mathrm{T}} \mathrm{H}_a^X$. Let $f$ be an order isomorphism of $\{b : b <_{\mathcal{O}}^X a\}$ onto $\{c : c <_{\mathcal{O}}^X a^*\}$. By arithmetical transfinite induction, we may assume that, for all $b <_{\mathcal{O}}^X a$, $\mathrm{H}_{f(b)}^X$ exists and is $=_{\mathrm{T}} \mathrm{H}_b^X$. If $|a|^X = 0$, it follows that $|a^*|^X = 0$ and by VIII.3.9.2 we have $\mathrm{H}_{a^*}^X =_{\mathrm{T}} X =_{\mathrm{T}} \mathrm{H}_a^X$. If $|a|^X = |b|^X + 1$ for some $b <_{\mathcal{O}}^X a$, it follows that $|a^*|^X = |c|^X + 1$ where $c = f(b) <_{\mathcal{O}}^X a^*$. Hence by VIII.3.9.3 we have that $\mathrm{H}_{a^*}^X$ exists and is $=_{\mathrm{T}} \mathrm{TJ}(\mathrm{H}_c^X) =_{\mathrm{T}} \mathrm{TJ}(\mathrm{H}_b^X) =_{\mathrm{T}} \mathrm{H}_a^X$. Suppose now that $|a|^X$ is a limit ordinal. By lemma VIII.3.10, the set

$$\begin{aligned}
\{(b, (c, m)) : b <_{\mathcal{O}}^X a \wedge c <_{\mathcal{O}}^X a^* \wedge \exists Y (Y =_{\mathrm{T}} \mathrm{H}_b^X \wedge \mathrm{H}(c, X, Y) \wedge m \in \mathrm{TJ}(Y))\}\\
= \{(b, (f(b), m)) : b <_{\mathcal{O}}^X a \wedge m \in \mathrm{TJ}(\mathrm{H}_{f(b)}^X)\}
\end{aligned}$$

exists and is $\leq_{\mathrm{T}} \mathrm{H}^X_a$. From this it follows easily that $\mathrm{H}^X_{a^*}$ exists and is $\leq_{\mathrm{T}} \mathrm{H}^X_a$. By symmetry $\mathrm{H}^X_{a^*} =_{\mathrm{T}} \mathrm{H}^X_a$ and the lemma is proved. □

Recall the discussion of comparability of countable well orderings in §§V.2 and V.6. The following lemma is a refinement of lemma V.2.9.

LEMMA VIII.3.14. *The following is provable in* $\mathsf{ACA}_0$. *Assume that* $\mathcal{O}(a, X)$ *and* $\mathcal{O}(a^*, X)$ *and that* $\mathrm{H}^X_a$ *exists. Then the countable well orderings* $\{b : b <^X_{\mathcal{O}} a\}$ *and* $\{c : c <^X_{\mathcal{O}} a^*\}$ *are comparable. Furthermore, the comparison map is* $\leq_{\mathrm{T}} \mathrm{H}^X_a$.

PROOF. Let $f$ be the set of pairs $(b, c)$ such that $b <^X_{\mathcal{O}} a$ and $c <^X_{\mathcal{O}} a^*$ and $\mathrm{H}^X_b =_{\mathrm{T}} \mathrm{H}^X_c$, i.e., $\exists Y\,(Y =_{\mathrm{T}} \mathrm{H}^X_b \wedge \mathrm{H}(c, X, Y))$. By lemma VIII.3.10, $f$ exists and is $\leq_{\mathrm{T}} \mathrm{H}^X_a$. By lemmas VIII.3.9 and VIII.3.13 and arithmetical transfinite induction (using $f$ as a parameter), it follows that either $f$ is an isomorphism of $\{b : b <^X_{\mathcal{O}} a\}$ onto $\{c : c <^X_{\mathcal{O}} a^*\}$, or $f$ is an isomorphism of $\{b : b <^X_{\mathcal{O}} a\}$ onto some initial section of $\{c : c <^X_{\mathcal{O}} a^*\}$, or $f$ is an isomorphism of some initial section of $\{b : b <^X_{\mathcal{O}} a\}$ onto $\{c : c <^X_{\mathcal{O}} a^*\}$. In any case $f$ is a comparison map from $\{b : b <^X_{\mathcal{O}} a\}$ to $\{c : c <^X_{\mathcal{O}} a^*\}$. This completes the proof. □

THEOREM VIII.3.15. $\mathsf{ATR}_0$ *is equivalent over* $\mathsf{ACA}_0$ *to*

$$\forall X\, \forall a\, (\mathcal{O}(a, X) \rightarrow \mathrm{H}^X_a \text{ exists}). \tag{22}$$

PROOF. If $\mathcal{O}(a, X)$ holds, the existence of $\mathrm{H}^X_a$ can be proved by a direct application of arithmetical transfinite recursion along the countable well ordering $\{b : b <^X_{\mathcal{O}} a\}$. This shows that $\mathsf{ATR}_0$ implies (22). Conversely, if (22) holds, then by lemma VIII.3.14 any two countable well orderings are comparable, and by theorem V.6.8 this implies arithmetical transfinite recursion. □

DEFINITION VIII.3.16. The following definition is made in $\mathsf{ACA}_0$. Given $X, Y \subseteq \mathbb{N}$, we say that $Y$ *is hyperarithmetical in* $X$, abbreviated $Y \leq_{\mathrm{H}} X$, if there exists $a$ such that $\mathcal{O}(a, X)$ holds and $\mathrm{H}^X_a$ exists and $Y \leq_{\mathrm{T}} \mathrm{H}^X_a$. We say that $Y$ *is hyperarithmetical* if $Y \leq_{\mathrm{H}} \emptyset$. (Here $\emptyset$ denotes the empty set.)

The following lemma will be useful in several places.

LEMMA VIII.3.17. *We can find a* $\Pi^1_1$ *formula* $\nu(i, X)$ *and a* $\Sigma^1_1$ *formula* $\alpha(i, X, Y)$, *with no free variables other than those displayed, such that* $\mathsf{ACA}_0$ *proves*

$$\forall X\, \forall Y\, (Y \leq_{\mathrm{H}} X \leftrightarrow \exists i\, (\nu(i, X) \wedge \alpha(i, X, Y)))$$

*and*

$$\forall X\, \forall i\, \forall Y\, \forall Y'\, ((\nu(i, X) \wedge \alpha(i, X, Y) \wedge \alpha(i, X, Y')) \rightarrow Y = Y'),$$

*while* $\mathsf{ATR}_0$ *proves*

$$\forall X\, \forall i\, (\nu(i, X) \rightarrow \exists Y\, \alpha(i, X, Y)).$$

PROOF. If $Y \leq_{\mathrm{H}} X$, then $Y \leq_{\mathrm{T}} \mathrm{H}_a^X$ where $\mathcal{O}(a, X)$ holds. In particular there exists $e$ such that $Y = (\mathrm{TJ}(\mathrm{H}_a^X))_e$. Let $\nu(i, X)$ say that $i$ is of the form $(a, e)$ where $\mathcal{O}(a, X)$ holds, and let $\alpha(i, X, Y)$ say that $\exists Z\,(\mathrm{H}(a, X, Z) \wedge Y = (\mathrm{TJ}(Z))_e)$ where $i = (a, e)$. The desired properties of the formulas $\nu(i, X)$ and $\alpha(i, X, Z)$ follow easily from lemma VIII.3.7. □

DEFINITION VIII.3.18 ($\Delta^1_1$ definability). The following definition is made in $\mathsf{ACA}_0$. Given $X, Y \subseteq \mathbb{N}$, we say that $Y$ *is* $\Sigma^1_1$ *in* $X$ if

$$\exists e\, \forall m\, (m \in Y \leftrightarrow \exists f\, \pi(e, m, X, f)).$$

Here $\pi(e, m_1, X_1, X_2)$ is a fixed universal lightface $\Pi^0_1$ formula as in the definition of the hyperjump (definition VII.1.5).

Note that, by the normal form theorem for $\Sigma^1_1$ relations (lemma V.1.4), $\exists f\, \pi(e, m, X, f)$ is a universal lightface $\Sigma^1_1$ formula. Thus $Y$ is $\Sigma^1_1$ in $X$ if and only if $Y = \{m : \varphi(m, X)\}$ for some $\Sigma^1_1$ formula $\varphi(m, X)$ with no free set variables (i.e., set parameters) other than $X$.

We say that $Y$ *is* $\Pi^1_1$ *in* $X$ if $\mathbb{N} \setminus Y$ is $\Sigma^1_1$ in $X$. We say that $Y$ *is* $\Delta^1_1$ *in* $X$ if $Y$ is both $\Sigma^1_1$ in $X$ and $\Pi^1_1$ in $X$.

The following theorem is the main result of this section.

THEOREM VIII.3.19 (Kleene/Souslin theorem in $\mathsf{ACA}_0$). *The following is provable in* $\mathsf{ACA}_0$. *Let* $X \subseteq \mathbb{N}$ *be such that* $\forall a\, (\mathcal{O}(a, X) \rightarrow \mathrm{H}_a^X$ *exists*). *Then for all* $Z \subseteq \mathbb{N}$, $Z$ *is hyperarithmetical in* $X$ *if and only if* $Z$ *is* $\Delta^1_1$ *in* $X$.

PROOF. We reason in $\mathsf{ACA}_0$. Suppose first that $Z$ is hyperarithmetical in $X$. Using the notation of lemma VIII.3.17, let $i$ be such that $\nu(i, X)$ and $\alpha(i, X, Z)$ hold. For all $m \in \mathbb{N}$ we have

$$\begin{aligned} m \in Z &\leftrightarrow \exists Y(\alpha(i, X, Y) \wedge m \in Y) \\ &\leftrightarrow \forall Y(\alpha(i, X, Y) \rightarrow m \in Y) \end{aligned}$$

which shows that $Z$ is $\Delta^1_1$ in $X$.

For the converse, assume that $Z$ is $\Delta^1_1$ in $X$, say $Z = \{m : \varphi(m, X)\} = \{m : \psi(m, X)\}$ where $\varphi(m, X)$ and $\psi(m, X)$ are respectively $\Sigma^1_1$ and $\Pi^1_1$ with no free set variables other than $X$. As in the proof of lemma VIII.3.4, let $\langle R^X_m : m \in X\rangle$ be an $X$-recursive sequence of $X$-recursive linear orderings such that

$$\forall m\, (\psi(m, X) \leftrightarrow R^X_m \text{ is a well ordering}).$$

We claim that the order types of the well ordered $R^X_m$'s are bounded. In other words, we claim that there exists an $a$ such that $\mathcal{O}(a, X)$ holds and $\forall m\, (R^X_m$ well ordered $\rightarrow R^X_m$ is isomorphic to some initial section of $\{b : b <^X_{\mathcal{O}} a\})$. Note first that our assumption $\forall a\, (\mathcal{O}(a, X) \rightarrow \mathrm{H}_a^X$ exists) implies by lemma VIII.3.14 that any two $X$-recursive well orderings are comparable. Now if our claim were false, then by comparability of $X$-recursive well orderings we would have $\forall a\, (\mathcal{O}(a, X) \leftrightarrow \varphi'(a, X))$ where $\varphi'(a, X)$ is $\Sigma^1_1$, namely $\varphi'(a, X) \equiv (\mathcal{O}_+(a, X) \wedge \exists m\, (\varphi(m, X) \wedge$ there exists

an isomorphism of $\{b : b <_{\mathcal{O}}^X a\}$ onto some initial section of $R_m^X$)). This would contradict lemma VIII.3.4.

Let $a$ be as in the previous claim. Then by lemma VIII.3.14 we have $\forall m\,(m \in Z \leftrightarrow (\exists f \leq_{\mathrm{T}} \mathrm{H}_a^X)\,(f$ is an isomorphism of $R_m^X$ onto some initial section of $\{b : b <_{\mathcal{O}}^X a\}))$. Thus $Z$ is arithmetically definable from $\mathrm{H}_a^X$. By sublemma VIII.3.11 it follows that $Z = (\mathrm{TJ}(k, \mathrm{H}_a^X))_e$ for some $k, e \in \mathbb{N}$. Letting $a^*$ be such that $\mathcal{O}(a^*, X)$ and $|a^*|^X = |a|^X + k$, it follows by lemmas VIII.3.13 and VIII.3.9.3 that $Z \leq_{\mathrm{T}} \mathrm{H}_{a^*}^X$. Thus $Z$ is hyperarithmetical in $X$. This completes the proof of the theorem. □

We shall now end this section by presenting two theorems about hyperarithmetical quantifiers. Given an $\mathrm{L}_2$-formula $\varphi$, we shall write $(\forall Y \leq_{\mathrm{H}} X)\varphi$ as an abbreviation for

$$\forall Y(Y \leq_{\mathrm{H}} X \to \varphi).$$

The expression $(\forall Y \leq_{\mathrm{H}} X)$ is known as a *hyperarithmetical quantifier*. The first of our two theorems says that the class of $\Sigma_1^1$ formulas is closed under universal hyperarithmetical quantification. The second theorem is a sort of converse to the first. We prove both theorems in $\mathsf{ATR}_0$.

THEOREM VIII.3.20 (hyperarithmetical quantifiers, 1). *For any $\Sigma_1^1$ formula $\varphi(X, Y)$, we can find a $\Sigma_1^1$ formula $\varphi'(X)$ such that $\mathsf{ATR}_0$ proves*

$$\varphi'(X) \leftrightarrow (\forall Y \leq_{\mathrm{H}} X)\varphi(X, Y).$$

(Note that $\varphi(X, Y)$ may contain free variables other than $X$ and $Y$. If this is the case, then $\varphi'(X)$ will also contain those free variables.)

PROOF. Using the notation of lemma VIII.3.17, we have

$$\begin{aligned}(\forall Y \leq_{\mathrm{H}} X)\varphi(X, Y) &\leftrightarrow \forall i\,(v(i, X) \to \exists Y\,(\alpha(i, X, Y) \wedge \varphi(X, Y))) \\ &\leftrightarrow \forall i\,\varphi''(i, X)\end{aligned}$$

where $\varphi''(i, X)$ is $\Sigma_1^1$. Our theorem therefore reduces to the following lemma.

LEMMA VIII.3.21. *For any $\Sigma_1^1$ formula $\varphi''(n)$, we can find a $\Sigma_1^1$ formula $\varphi'$ such that $\varphi' \leftrightarrow \forall n\,\varphi''(n)$ is provable in $\mathsf{ATR}_0$ (actually in $\Sigma_1^1$-$\mathsf{AC}_0$).*

(Note that $\varphi''(n)$ may contain free variables other than $n$. In this case $\varphi'$ will also contain those free variables. See also lemma VIII.6.2.)

PROOF. Let us write $\varphi''(n) \equiv \exists Z\,\theta(n, Z)$ where $\theta$ is arithmetical and $Z$ is a set variable. Recall from theorem V.8.3 that the $\Sigma_1^1$ axiom of choice is provable in $\mathsf{ATR}_0$. (See also §VII.6.) By $\Sigma_1^1$ choice we have

$$\begin{aligned}\forall n\,\varphi''(n) &\leftrightarrow \forall n\,\exists Z\,\theta(n, Z) \\ &\leftrightarrow \exists W\,\forall n\,\theta(n, (W)_n)\end{aligned}$$

and the latter expression is $\Sigma_1^1$. This proves lemma VIII.3.21 and theorem VIII.3.20. □ □

The rest of this section is devoted to a proof of a sort of converse to theorem VIII.3.20 (see theorem VIII.3.27 below).

LEMMA VIII.3.22. *The following is provable in* $\mathsf{ACA}_0$. *Assume that* $\mathcal{O}(a, X)$ *holds and that* $|a|^X$ *is a limit ordinal. Let* $A$ *be a set such that* $\forall b\,(b <^X_{\mathcal{O}} a \to \mathrm{H}^X_b$ *exists and is* $\leq_{\mathrm{T}} A)$. *Then* $\mathrm{H}^X_a$ *exists and is* $\leq_{\mathrm{T}} \mathrm{TJ}(2, A)$.

PROOF. We have $(m, b+1) \in \mathrm{H}^X_a$ if and only if

$$(\exists Y \leq_{\mathrm{T}} A)\,(\mathrm{H}(b, X, Y) \wedge m \in \mathrm{TJ}(Y)).$$

Thus $\mathrm{H}^X_a$ is uniformly arithmetically definable from A. Hence by sublemma VIII.3.11 we can find a fixed $k < \omega$ such that our lemma holds with $k$ in place of 2. A more careful computation shows that $\mathrm{H}^X_a$ is $\Delta^0_3$ in A, hence by the proof of sublemma VIII.3.11 our lemma holds with $k = 2$. (In the application of our lemma to be made below, only the finiteness of $k$ is important.) □

LEMMA VIII.3.23. *The following is provable in* $\mathsf{ACA}_0$. *Let* $\langle A_n : n \in \mathbb{N}\rangle$ *be a sequence of sets such that* $\forall n\,(\mathrm{TJ}(A_{n+1}) \leq_{\mathrm{T}} A_n)$, *and let* $X$ *be a set such that* $\forall n\,(X \leq_{\mathrm{T}} A_n)$. *Then*

$$\forall a\,(\mathcal{O}(a, X) \to \mathrm{H}^X_a \text{ exists})$$

*and*

$$\forall Y\,(Y \leq_{\mathrm{H}} X \to \forall n\,(Y \leq_{\mathrm{T}} A_n)).$$

*In particular, none of the sets* $A_n$ *is hyperarithmetical in* $X$.

PROOF. Fix $X$ and let $a$ be such that $\mathcal{O}(a, X)$ holds. We wish to prove that $\mathrm{H}^X_a$ exists and is $\leq_{\mathrm{T}} A_n$ for all $n$. This assertion is arithmetical so we may prove it by arithmetical transfinite induction. If $|a|^X = 0$, we have by VIII.3.9.2 $\mathrm{H}^X_a =_{\mathrm{T}} X \leq_{\mathrm{T}} A_n$ for all $n$. If $|a|^X = |b|^X + 1$ for some $b <^X_{\mathcal{O}} a$, we have inductively $\mathrm{H}^X_b \leq_{\mathrm{T}} A_n$ for all $n$, hence by VIII.3.9.3 $\mathrm{H}^X_a =_{\mathrm{T}} \mathrm{TJ}(\mathrm{H}^X_b) \leq_{\mathrm{T}} \mathrm{TJ}(A_{n+1}) \leq_{\mathrm{T}} A_n$ for all $n$. If $|a|^X$ is a limit ordinal, we have inductively $\mathrm{H}^X_b \leq_{\mathrm{T}} A_n$ for all $b <^X_{\mathcal{O}} a$ and all $n$, hence by the previous lemma $\mathrm{H}^X_a \leq_{\mathrm{T}} \mathrm{TJ}(2, A_{n+2}) \leq_{\mathrm{T}} A_n$ for all $n$. This completes the proof. □

LEMMA VIII.3.24. *The following is provable in* $\mathsf{ACA}_0$. *Fix* $X \subseteq \mathbb{N}$ *and assume that* $\forall a\,(\mathcal{O}(a, X) \to \mathrm{H}^X_a$ *exists*). *Then there exists* $a^*$ *such that*

$$\mathcal{O}_+(a^*, X) \wedge \exists Y\,\mathrm{H}(a^*, X, Y) \wedge \neg\mathcal{O}(a^*, X).$$

PROOF. (This is really a special case of lemma V.4.12 on the existence of pseudohierarchies.) Let $\mathcal{O}_1(a, X)$ be the formula $\mathcal{O}_+(a, X) \wedge \exists Y\,\mathrm{H}(a, X, Y)$. By assumption we have $\forall a\,(\mathcal{O}(a, X) \to \mathcal{O}_1(a, X))$. Since $\mathcal{O}_1(a, X)$ is $\Sigma^1_1$, we have by lemma VIII.3.4 $\neg\forall a\,(\mathcal{O}(a, X) \leftrightarrow \mathcal{O}_1(a, X))$, hence $\exists a\,(\mathcal{O}_1(a, X) \wedge \neg\mathcal{O}(a, X))$. Letting $a^*$ be any such $a$, we obtain the desired conclusion. □

LEMMA VIII.3.25. *The following is provable in* $\mathsf{ACA}_0$. *Suppose that* $\mathcal{O}_+(a, X) \wedge \mathrm{H}(a, X, Y) \wedge \neg\mathcal{O}(a, X)$ *holds. Then* $Y$ *is not hyperarithmetical in* $X$. *In fact, we have* $\forall Z\,(Z \leq_{\mathrm{H}} X \to Z \leq_{\mathrm{T}} Y)$.

PROOF. For each $b \leq^X_{\mathcal{O}} a$ put

$$Y_b = \{(m,0)\colon (m,0) \in Y\} \cup \{(m, c+1)\colon c <^X_{\mathcal{O}} b \wedge (m, c+1) \in Y\}.$$

Then $Y_a = Y$ and, for all $c <^X_{\mathcal{O}} b \leq^X_{\mathcal{O}} a$, $(Y_b)_{c+1} = \mathrm{TJ}(Y_c)$. Since $\neg\mathcal{O}(a, X)$ holds, there exists a descending sequence

$$a = a_0 >^X_{\mathcal{O}} a_1 >^X_{\mathcal{O}} \cdots >^X_{\mathcal{O}} a_n >^X_{\mathcal{O}} \cdots .$$

Setting $A_n = Y_{a_n}$, we have $X \leq_{\mathrm{T}} A_n$ and $\mathrm{TJ}(A_{n+1}) \leq_{\mathrm{T}} A_n$ for all $n$. By lemma VIII.3.23, the desired conclusions follow. □

LEMMA VIII.3.26. *In* $\mathsf{ATR}_0$ *we have*

$$\forall X\,\forall a\,(\mathcal{O}(a, X) \leftrightarrow (\exists Y \leq_{\mathrm{H}} X)\,\mathrm{H}(a, X, Y)).$$

PROOF. If $\mathcal{O}(a, X)$ holds, then obviously $Y = \mathrm{H}^X_a$ satisfies $Y \leq_{\mathrm{H}} X$ and $\mathrm{H}(a, X, Y)$. Conversely, suppose that $\mathrm{H}(a, X, Y)$ holds and $Y \leq_{\mathrm{H}} X$. Then $\mathcal{O}(a, X)$ follows by lemma VIII.3.25. This completes the proof. □

THEOREM VIII.3.27 (hyperarithmetical quantifiers, 2). *Let* $\varphi(X)$ *be a* $\Sigma^1_1$ *formula with no free set variables other than* $X$. *Then we can find an arithmetical formula* $\theta(X, Z)$ *such that* $\mathsf{ATR}_0$ *proves*

$$\forall X\,(\varphi(X) \leftrightarrow (\forall Z \leq_{\mathrm{H}} X)\,\theta(X, Z)).$$

PROOF. For simplicity, assume that $\varphi(X)$ has only one free number variable, call it $m$. The formula $\neg\varphi(m, X)$ is $\Pi^1_1$, so as in the proof of lemma VIII.3.4 we can find an $X$-recursive sequence of $X$-recursive linear orderings $\langle R^X_m\colon m \in \mathbb{N}\rangle$ such that $\forall X\,\forall m\,(\varphi(m, X) \leftrightarrow R^X_m$ is not a well ordering). Now for any particular $m$ and $X$, $R^X_m$ is isomorphic to $\{b\colon b <^X_{\mathcal{O}} a\}$ for some $a \in \mathcal{O}^X_+$. If moreover $R^X_m$ is a well ordering, then $\mathcal{O}(a, X)$ holds and by lemma VIII.3.14 the isomorphism of $R^X_m$ onto $\{b\colon b <^X_{\mathcal{O}} a\}$ is $\leq_{\mathrm{H}} X$. Thus we have

$$\begin{aligned}
&\neg\varphi(m, X)\\
&\qquad \leftrightarrow R^X_m \text{ is a well ordering}\\
&\qquad \leftrightarrow \exists a\,(\mathcal{O}(a, X) \wedge (\exists f \leq_{\mathrm{H}} X)\,(f\colon |R^X_m| = |a|^X))\\
&\qquad \leftrightarrow \exists a\,((\exists Y \leq_{\mathrm{H}} X)\,\mathrm{H}(a, X, Y) \wedge (\exists f \leq_{\mathrm{H}} X)\,(f\colon |R^X_m| = |a|^X))
\end{aligned}$$

where the last equivalence follows from lemma VIII.3.26. We now have

$$\neg\varphi(m, X) \leftrightarrow (\exists Z \leq_{\mathrm{H}} X)\,\psi(m, X, Z)$$

where $\psi(m, X, Z) \equiv (Z$ encodes a triple $(a, Y, f)$ such that $\mathrm{H}(a, X, Y)$ and $f\colon |R^X_m| = |a|^X)$. Note that $\psi(m, X, Z)$ is arithmetical. Setting $\theta(m, X, Z) \equiv \neg\psi(m, X, Z)$, we obtain $\varphi(m, X) \leftrightarrow (\forall Z \leq_{\mathrm{H}} X)\,\theta(m, X, Z)$. This completes the proof. □

**Notes for §VIII.3.** Our exposition of hyperarithmetical theory here is somewhat idiosyncratic in that it avoids the use of the recursion theorem. An orthodox exposition is in Sacks [211, part A]. Other relevant references are Harrison [106] and Steel [255].

Historically, hyperarithmetical theory is the creation of Davis, Mostowski, and Kleene. (For bibliographical references, see Spector [253].) The fact that $|a|^X = |b|^X$ implies $\mathrm{H}^X_a =_{\mathrm{T}} \mathrm{H}^X_b$ is due to Spector [253]. The so-called Kleene/Souslin theorem $\Delta^1_1(X) = \mathrm{HYP}(X)$ is due to Kleene [144]. The hyperarithmetical quantifier theorem $\Pi^1_1(X) = (\Sigma^1_1)^{\mathrm{HYP}(X)}$ is due to Spector [254] and Gandy [88].

An important feature of this section is that we have shown how to formalize hyperarithmetical theory within relatively weak subsystems of $\mathsf{Z}_2$. Such formalization was apparently first undertaken by Friedman [62, chapter II]. This eventually led to the discovery of the system $\mathsf{ATR}_0$. See Steel [256], Friedman [68, 69], and Friedman/McAloon/Simpson [76].

## VIII.4. $\omega$-Models of $\Sigma^1_1$ Choice

Recall from §§VII.5 and VII.6 that $\Delta^1_1$-$\mathsf{CA}_0$, $\Sigma^1_1$-$\mathsf{AC}_0$, and $\Sigma^1_1$-$\mathsf{DC}_0$ are the subsystems of second order arithmetic with $\Delta^1_1$ comprehension, $\Sigma^1_1$ choice, and $\Sigma^1_1$ dependent choice. The purpose of this section is to discuss $\omega$-models of these three systems. We show that all three systems have the same minimum (i.e., unique smallest) $\omega$-model, namely

$$\mathrm{HYP} = \{X \subseteq \omega \colon X \text{ is hyperarithmetical}\}$$

(corollary VIII.4.17). In addition, we show that $\mathsf{ATR}_0$ proves the existence of countable coded $\omega$-models of all three systems (theorem VIII.4.20).

LEMMA VIII.4.1. $\mathsf{ATR}_0$ *proves* $\Delta^1_1$ *comprehension and* $\Sigma^1_1$ *choice.*

PROOF. This follows from theorem V.8.3 and lemma VII.6.6.1. □

REMARK VIII.4.2. We shall see later (theorem VIII.5.13) that $\mathsf{ATR}_0$ does not prove $\Sigma^1_1$ dependent choice.

DEFINITION VIII.4.3 (relativization to $\mathrm{HYP}(X)$). For any set variable $X$ and any $\mathrm{L}_2$-formula $\varphi$ in which $X$ does not occur quantified, let $\varphi^{\mathrm{HYP}(X)}$ be the $\mathrm{L}_2$-formula which is obtained from $\varphi$ by relativizing all of the set quantifiers in $\varphi$ to sets which are hyperarithmetical in $X$. Thus each quantifier $\forall Y$ is replaced by $(\forall Y \leq_{\mathrm{H}} X)$, etc. (See the discussion of hyperarithmetical quantifiers, at the end of the previous section.) The formula $\varphi^{\mathrm{HYP}(X)}$ is called *the relativization of* $\varphi$ *to* $\mathrm{HYP}(X)$. We sometimes express $\varphi^{\mathrm{HYP}(X)}$ by saying that $\mathrm{HYP}(X)$ *satisfies* $\varphi$.

REMARK VIII.4.4. Note that $\mathsf{ATR}_0$ is not strong enough to prove the existence of the countable coded $\omega$-model

$$\mathrm{HYP}(X) = \{ Y \subseteq \mathbb{N} \colon Y \leq_{\mathrm{H}} X \}$$

consisting exactly of those sets $Y$ which are hyperarithmetical in a given set $X$. (To see this, let $M$ be a countable $\beta$-model of $\mathsf{ATR}_0$ such that $X \in M$ and $\mathrm{HJ}(X) \notin M$, as in corollary VII.2.12. If $M$ were to contain a code for the countable $\omega$-model $\mathrm{HYP}(X)$, it would follow by theorem VIII.3.27 that $\mathrm{HJ}(X) \in M$, a contradiction.)

Nevertheless, we can use relativization (definition VIII.4.3) to state the following as a theorem of $\mathsf{ATR}_0$.

THEOREM VIII.4.5 ($\Delta^1_1$ comprehension in $\mathrm{HYP}(X)$). *The following is provable in* $\mathsf{ATR}_0$. *For any* $X \subseteq \mathbb{N}$, $\mathrm{HYP}(X)$ *satisfies* $\Delta^1_1$ *comprehension. In other words, we have*

$$\forall X \, (\Delta^1_1 \text{ comprehension})^{\mathrm{HYP}(X)}.$$

PROOF. Assume

$$\forall n (\varphi(n) \leftrightarrow \psi(n))^{\mathrm{HYP}(X)}$$

where $\varphi(n)$ is $\Sigma^1_1$, $\psi(n)$ is $\Pi^1_1$, and all of the set parameters in $\varphi(n)$ and $\psi(n)$ are hyperarithmetical in $X$. Write $\varphi(n) \equiv \exists Y \varphi'(n, Y)$ and $\psi(n) \equiv \forall Y \psi'(n, Y)$, where $\varphi'(n, Y)$ and $\psi'(n, Y)$ are arithmetical. Thus $\varphi(n)^{\mathrm{HYP}(X)} \equiv (\exists Y \leq_{\mathrm{H}} X) \varphi'(Y, n)$ and $\psi(n)^{\mathrm{HYP}(X)} \equiv (\forall Y \leq_{\mathrm{H}} X) \psi'(Y, n)$. By theorem VIII.3.20, $(\exists Y \leq_{\mathrm{H}} X) \varphi'(Y, n)$ is equivalent to a $\Pi^1_1$ formula $\varphi''(X, n)$, and similarly $(\forall Y \leq_{\mathrm{H}} X) \psi'(Y, n)$ is equivalent to a $\Sigma^1_1$ formula $\psi''(X, n)$, where $\varphi''(X, n)$ and $\psi''(X, n)$ contain no free set variables other than $X$. Our assumption $\forall n \, (\varphi(n) \leftrightarrow \psi(n))^{\mathrm{HYP}(X)}$ now reads $\forall n \, (\varphi''(X, n) \leftrightarrow \psi''(X, n))$. Hence by $\Delta^1_1$ comprehension (lemma VIII.4.1) there exists $Z$ such that $\forall n \, (n \in Z \leftrightarrow \varphi''(X, n))$, and by theorem VIII.3.19 this $Z$ is hyperarithmetical in $X$. Thus we have

$$(\exists Z \, \forall n \, (n \in Z \leftrightarrow \varphi(n)))^{\mathrm{HYP}(X)}$$

and the theorem is proved. □

Our next goal is to strengthen the previous theorem by showing that $\mathrm{HYP}(X)$ satisfies the $\Sigma^1_1$ axiom of choice and indeed $\Sigma^1_1$ dependent choice.

LEMMA VIII.4.6 ($\Pi^1_1$ uniformization). *Let* $\psi(i)$ *be a* $\Pi^1_1$ *formula with a distinguished free number variable* $i$. *Then we can effectively find a* $\Pi^1_1$ *formula* $\widehat{\psi}(i)$ *such that* $\mathsf{ATR}_0$ *proves*

(1) $\forall i \, (\widehat{\psi}(i) \to \psi(i))$,
(2) $\forall i \, (\psi(i) \to \exists j \, \widehat{\psi}(j))$,
(3) $\forall i \, \forall j \, ((\widehat{\psi}(i) \wedge \widehat{\psi}(j)) \to i = j)$.

PROOF. For simplicity, assume that $\psi(i) \equiv \psi(i, X)$ has only one free set variable, $X$. As in the proof of lemma VIII.3.4, we can effectively find an

$X$-recursive sequence of $X$-recursive linear orderings $\langle R^X_i : i \in \mathbb{N}\rangle$ such that

$$\forall i\,(\psi(i, X) \leftrightarrow R^X_i \text{ is a well ordering}).$$

Let $\widehat{\psi}(j, X)$ be the $\Pi^1_1$ formula

$$R^X_j \text{ is a well ordering} \wedge \neg\exists k\,|R^X_k| < |R^X_j| \wedge \neg(\exists k < j)\,|R^X_k| = |R^X_j|.$$

(See definition V.2.7.) Trivially we have (1) and (3). To prove (2) within $\mathsf{ATR}_0$, fix an $i$ such that $\psi(i)$ holds. Recall that $\mathsf{ATR}_0$ proves comparability of countable well orderings (lemma V.2.9). Hence for all $j$ we have: either $R^X_j$ is not a well ordering, or $|R^X_j| \geq |R^X_i|$, or $R^X_j$ is isomorphic to a unique initial section of $R^X_i$. Hence by $\Sigma^1_1$ choice (lemma VIII.4.1), there exists a set $A$ consisting of all $n \in \text{field}(R^X_i)$ such that $\exists j$ ($R^X_j$ is isomorphic to the initial section of $R^X_i$ determined by $n$). If $A$ is the empty set, let $j_0$ be the least $j$ such that $|R^X_i| = |R^X_j|$. Otherwise, since $R^X_i$ is a well ordering, let $n_0$ be the $R^X_i$-least element of $A$, and then let $j_0$ be the least $j$ such that $R^X_j$ is isomorphic to the initial section of $R^X_i$ determined by $n_0$. In either case we clearly have $\widehat{\psi}(j_0, X)$, so (2) is proved. This completes the proof of lemma VIII.4.6. □

LEMMA VIII.4.7. *Let $\psi(n, i, X)$ be a $\Pi^1_1$ formula with no free set variables other than $X$. Then $\mathsf{ATR}_0$ proves*

$$\forall n\,\exists i\,\psi(n, i, X) \rightarrow (\exists f \leq_{\mathrm{H}} X)\,\forall n\,\psi(n, f(n), X).$$

PROOF. By lemma VIII.4.6, let $\widehat{\psi}(n, i, X)$ be a $\Pi^1_1$ formula such that $\mathsf{ATR}_0$ proves $\widehat{\psi}(n, i, X) \rightarrow \psi(n, i, X)$ and $\psi(n, i, X) \rightarrow \exists j\,\widehat{\psi}(n, j, X)$ and $(\widehat{\psi}(n, i, X) \wedge \widehat{\psi}(n, j, X)) \rightarrow i = j$. Reasoning within $\mathsf{ATR}_0$, assume $\forall n\,\exists i\,\psi(n, i, X)$. It follows that $\forall n$ ($\exists$ exactly one $i$) $\widehat{\psi}(n, i, X)$. Hence, for any pair $(n, i)$, the $\Pi^1_1$ assertion $\widehat{\psi}(n, i, X)$ is equivalent to the $\Sigma^1_1$ assertion $\forall j\,(j \neq i \rightarrow \neg\widehat{\psi}(n, i, X))$. (The latter assertion is $\Sigma^1_1$ by lemma VIII.3.21.) Hence by $\Delta^1_1$ comprehension (lemma VIII.4.1) there exists a function $f : \mathbb{N} \rightarrow \mathbb{N}$ such that $\forall m\,(f(m)$ is the unique $i$ such that $\widehat{\psi}(m, i, X))$. Furthermore by theorem VIII.3.19 this $f$ is hyperarithmetical in $X$. The proof of the lemma is complete. □

THEOREM VIII.4.8 ($\Sigma^1_1$ choice in $\mathrm{HYP}(X)$). *The following is provable in $\mathsf{ATR}_0$. For any $X \subseteq \mathbb{N}$, $\mathrm{HYP}(X)$ satisfies the $\Sigma^1_1$ axiom of choice. In other words, we have*

$$\forall X\,(\Sigma^1_1 \text{ choice})^{\mathrm{HYP}(X)}.$$

PROOF. Assume $(\forall n\,\exists Y\,\eta(n, Y))^{\mathrm{HYP}(X)}$ where the formula $\eta(n, Y)$ is $\Sigma^1_1$ and all set parameters in it are $\leq_{\mathrm{H}} X$. By theorem VIII.3.20 we have

$$\forall n\,(\forall Y \leq_{\mathrm{H}} X)\,(\eta(n, Y)^{\mathrm{HYP}(X)} \leftrightarrow \eta'(n, X, Y))$$

where $\eta'(n, X, Y)$ is $\Pi^1_1$ with no free set variables other than $X$ and $Y$. Thus our assumption becomes $\forall n\,(\exists Y \leq_{\mathrm{H}} X)\,\eta'(n, X, Y)$. Using the notation of lemma VIII.3.17, we may expand this as

$$\forall n\,\exists i\,(\nu(i, X) \wedge \forall Y(\alpha(i, X, Y) \rightarrow \eta'(n, X, Y))),$$

or in other words $\forall n\,\exists i\,\psi(n, i, X)$ where $\psi(n, i, X)$ is $\Pi^1_1$ with no free set variables other than $X$. Applying lemma VIII.4.7, we obtain a function $f \leq_{\mathrm{H}} X$ such that $\forall n\,\psi(n, f(n), X)$ holds. Now for all $n$ and $k$, the $\Sigma^1_1$ condition $\exists Y\,(\alpha(f(n), X, Y) \wedge k \in Y)$ is equivalent to the $\Pi^1_1$ condition $\forall Y\,(\alpha(f(n), X, Y) \rightarrow k \in Y)$. Hence by $\Delta^1_1$ comprehension (lemma VIII.4.1), there exists a set $Z$ such that

$$\forall k\,\forall n\,((k, n) \in Z \leftrightarrow \exists Y\,(\alpha(f(n), X, Y) \wedge k \in Y)).$$

which implies $\forall n\,\eta'(n, X, (Z)_n)$. Thus, for all $n$, $(Z)_n$ is the unique $Y$ such that $\alpha(f(n), X, Y)$ holds. Furthermore, by theorem VIII.3.19, $Z$ is hyperarithmetical in $X$. Thus we conclude $(\exists Z\,\forall n\,\eta(n, (Z)_n))^{\mathrm{HYP}(X)}$ and our theorem is proved. □

Recall from §VII.6 that $\Sigma^1_1$-IND is the scheme of $\Sigma^1_1$ induction, i.e.,

$$(\varphi(0) \wedge \forall n\,(\varphi(n) \rightarrow \varphi(n+1))) \rightarrow \forall n\,\varphi(n)$$

where $\varphi(n)$ is any $\Sigma^1_1$ formula. We define $\Pi^1_1$-IND similarly.

LEMMA VIII.4.9. $\Sigma^1_1$-IND *is equivalent over* $\mathsf{RCA}_0$ *to* $\Pi^1_1$-IND.

PROOF. Assume $\Sigma^1_1$ induction. Suppose $\forall n\,(\psi(n) \rightarrow \psi(n+1))$ and $\neg\psi(k)$, where $\psi(n)$ is a $\Pi^1_1$ formula. Applying $\Sigma^1_1$ induction to the formula $n \leq k \rightarrow \neg\psi(k-n)$, we obtain $\forall n\,(n \leq k \rightarrow \neg\psi(k-n))$ so in particular $\neg\psi(0)$ holds. This proves $\Pi^1_1$ induction. The proof of the converse is similar. □

LEMMA VIII.4.10. *Let* $\varphi(m, X)$ *and* $\psi(m, n, X)$ *be* $\Pi^1_1$ *formulas with no free set variable other than* $X$. *Then* $\mathsf{ATR}_0$ *plus* $\Sigma^1_1$-IND *proves*

$$\begin{aligned}&\forall m\,[\varphi(m, X) \rightarrow \exists n\,[\varphi(n, X) \wedge \psi(m, n, X)]] \rightarrow \\ &\quad \forall m\,[\varphi(m, X) \rightarrow (\exists f \leq_{\mathrm{H}} X)\,[f(0) = m \wedge \forall i\,[\varphi(f(i), X) \wedge \\ &\qquad\qquad \psi(f(i), f(i+1), X)]]].\end{aligned}$$

PROOF. We reason in $\mathsf{ATR}_0$. Assume

$$\forall m\,[\varphi(m, X) \rightarrow \exists n\,[\varphi(n, X) \wedge \psi(m, n, X)]].$$

By $\mathsf{ATR}_0$ and lemma VIII.4.6, we may also assume $\forall m\,[\varphi(m, X) \rightarrow (\exists \text{ exactly one } n)\,\psi(m, n, X)]$. Fix $m$ such that $\varphi(m, X)$ holds. Let $\theta(k, \sigma)$ say that $\sigma$ is a finite sequence of length $k+1$ such that $\sigma(0) = m$ and $(\forall i < k)\,[\varphi(\sigma(i), X) \wedge \psi(\sigma(i), \sigma(i+1), X)]$. By lemma VIII.3.21, $\exists\sigma\,\theta(k, \sigma)$ is equivalent to a $\Pi^1_1$ formula. Thus we can use $\Pi^1_1$ induction (a consequence of $\Sigma^1_1$ induction by lemma VIII.4.9) to prove

$\forall k\,\exists\sigma\,\theta(k,\sigma)$. Moreover, it is easily proved that $\sigma$ is unique, i.e., $\forall k$ ($\exists$ exactly one $\sigma$) $\theta(k,\sigma)$. Hence by $\Delta^1_1$ comprehension (lemma VIII.4.1), there exists a unique function $f\colon \mathbb{N} \to \mathbb{N}$ such that $f(0) = m$ and $\forall i\,[\varphi(f(i), X) \wedge \psi(f(i), f(i+1), X)]$. Since $X$ is the only free set variable in the formulas $\varphi(m, X)$ and $\psi(m, n, X)$, it follows by lemma VIII.3.21 that $f$ is $\Delta^1_1$ in $X$. Hence by theorem VIII.3.19 $f$ is hyperarithmetical in $X$. This proves the lemma. □

THEOREM VIII.4.11 ($\Sigma^1_1$ dependent choice in $\mathrm{HYP}(X)$). *The following is provable in* $\mathsf{ATR}_0$ *plus* $\Sigma^1_1$-IND. *For any* $X \subseteq \mathbb{N}$, $\mathrm{HYP}(X)$ *satisfies the scheme of* $\Sigma^1_1$ *dependent choice. In other words, we have*

$$\forall X\,(\Sigma^1_1 \text{ dependent choice})^{\mathrm{HYP}(X)}.$$

PROOF. We proceed as in the proof of theorem VIII.4.8. Assume

$$(\forall n\,\forall Y \exists Z\,\eta(n, Y, Z))^{\mathrm{HYP}(X)}$$

where $\eta(n, Y, Z)$ is $\Sigma^1_1$ and all set parameters in it are $\leq_{\mathrm{H}} X$. By theorem VIII.3.20, we have

$$\forall n\,(\forall Y \leq_{\mathrm{H}} X)\,(\forall Z \leq_{\mathrm{H}} X)\,[\eta(n, Y, Z)^{\mathrm{HYP}(X)} \leftrightarrow \eta'(n, X, Y, Z)]$$

where $\eta'(n, X, Y, Z)$ is $\Pi^1_1$ with no free set variables other than $X$, $Y$ and $Z$. Thus our assumption becomes

$$\forall n\,(\forall Y \leq_{\mathrm{H}} X)\,(\exists Z \leq_{\mathrm{H}} X)\,\eta'(n, X, Y, Z).$$

Using the notation of lemma VIII.3.17, we may expand this as

$$\forall n\,\forall i\,[v(i, X) \to \exists j\,[v(j, X) \wedge \forall Y\,\forall Z\,[(\alpha(i, X, Y) \wedge \alpha(j, X, Z)) \to \eta'(n, X, Y, Z)]]].$$

Applying lemma VIII.4.10, we obtain a function $f \leq_{\mathrm{H}} X$ such that

$$\forall n\,[v(f(n), X) \wedge \forall Y\,\forall Z\,[(\alpha(f(n), X, Y) \wedge \alpha(f(n+1), X, Z)) \to [Y = (Z)^n \wedge Z = (Z)^{n+1} \wedge (\forall m \leq n)\,\eta'(m, X, (Z)^m, (Z)_m)]]]$$

holds. As in the last part of the proof of theorem VIII.4.8, we can now use $\Delta^1_1$ comprehension to obtain a set $W$ such that $\forall n\,[(W)^n$ is the unique $Z$ such that $\alpha(f(n), X, Z)]$. By theorem VIII.3.19, $W$ is hyperarithmetical in $X$. Thus we conclude

$$(\exists W\,\forall n\,\eta(n, (W)^n, (W)_n))^{\mathrm{HYP}(X)}$$

and theorem VIII.4.11 is proved. □

Having shown that $\mathrm{HYP}(X)$ is an $\omega$-model of $\Sigma^1_1$ choice (indeed $\Sigma^1_1$ dependent choice), our next goal is to show that $\mathrm{HYP}(X)$ is the smallest such model which contains $X$. Actually we shall obtain a sharper result by considering a weaker choice scheme, introduced in the following definition.

DEFINITION VIII.4.12 (weak $\Sigma^1_1$ choice). *Weak* $\Sigma^1_1$-$\mathsf{AC}_0$ is the $\mathrm{L}_2$-theory whose axioms are those of $\mathsf{ACA}_0$ plus the scheme of *weak* $\Sigma^1_1$ *choice*, i.e.,

$$\forall n\,(\exists \text{ exactly one } Y)\,\theta(n, Y) \to \exists Z\,\forall n\,\theta(n, (Z)_n)$$

where $\theta(n, Y)$ is any arithmetical formula in which $Z$ does not occur.

REMARK VIII.4.13. It is clear that $\Sigma^1_1$ choice implies weak $\Sigma^1_1$ choice. (Compare definition VII.6.1.1.)

EXERCISE VIII.4.14. Show that $\Delta^1_1$ comprehension implies weak $\Sigma^1_1$ choice.

LEMMA VIII.4.15. *The following is provable in* $\mathsf{ACA}_0$. *Let $M$ be a countable coded $\omega$-model of weak* $\Sigma^1_1$-$\mathsf{AC}_0$. *Then for all $X \in M$ we have*

$$\forall a\,(\mathcal{O}(a, X) \to (\mathrm{H}^X_a \text{ exists} \wedge \mathrm{H}^X_a \in M)).$$

*Moreover $M$ is closed under relative hyperarithmeticity, i.e., $X \in M$, $Y \leq_{\mathrm{H}} X$ imply $Y \in M$.*

PROOF. Let $M$ be a countable coded $\omega$-model of weak $\Sigma^1_1$-$\mathsf{AC}_0$. Let $X \in M$ be given. If $\mathcal{O}(a, X)$ holds, the statement

$$b \leq^X_{\mathcal{O}} a \wedge \mathrm{H}^X_b \text{ exists} \wedge \mathrm{H}^X_b \in M$$

is arithmetical in the code for $M$ and may therefore be proved by arithmetical transfinite induction along $\{b : b \leq^X_{\mathcal{O}} a\}$. Assume now that $\mathrm{H}^X_c$ exists and $\in M$ for all $c <^X_{\mathcal{O}} b$. Hence, by lemma VIII.3.7, $M$ satisfies

$$\forall c\,(c <^X_{\mathcal{O}} b \to (\exists \text{ exactly one } Y)\,\mathrm{H}(c, X, Y)).$$

By weak $\Sigma^1_1$ choice within $M$, it follows that $M$ satisfies

$$\exists Z\,\forall c\,(c <^X_{\mathcal{O}} b \to \mathrm{H}(c, X, (Z)_c)).$$

Hence, by arithmetical comprehension within $M$, we see that $M$ satisfies $\exists Y\,\mathrm{H}(b, X, Y)$. This implies that $\mathrm{H}^X_b$ exists and $\in M$. We have now shown

$$\forall a\,(\mathcal{O}(a, X) \to (\mathrm{H}^X_a \text{ exists} \wedge \mathrm{H}^X_a \in M)).$$

From this and the fact that $M$ is closed under relative recursiveness, it follows that $M$ is closed under relative hyperarithmeticity. Lemma VIII.4.15 is proved. □

THEOREM VIII.4.16. *The following is provable in* $\Pi^1_1$-$\mathsf{CA}_0$. *For all $X \subseteq \mathbb{N}$,* $\mathrm{HYP}(X)$ *can be characterized as the smallest countable coded $\omega$-model of weak* $\Sigma^1_1$-$\mathsf{AC}_0$ (*or of* $\Delta^1_1$-$\mathsf{CA}_0$, *or of* $\Sigma^1_1$-$\mathsf{AC}_0$, *or of* $\Sigma^1_1$-$\mathsf{DC}_0$) *which contains $X$.*

PROOF. Since the formula $\mathcal{O}(a, X)$ is $\Pi^1_1$, it is clear by $\Pi^1_1$ comprehension that the countable coded $\omega$-model

$$\mathrm{HYP}(X) = \{Y : Y \leq_{\mathrm{H}} X\}$$

exists. By theorems VIII.4.8 and VIII.4.11, it follows that $\mathrm{HYP}(X)$ is an $\omega$-model of $\Sigma^1_1$-$\mathsf{DC}_0$, etc. By lemma VIII.4.15 $\mathrm{HYP}(X)$ is the smallest such model which contains $X$. □

COROLLARY VIII.4.17 (minimum $\omega$-model of $\Sigma^1_1$-$\mathsf{AC}_0$, etc.). *The systems* $\Sigma^1_1$-$\mathsf{DC}_0$, $\Sigma^1_1$-$\mathsf{AC}_0$, $\Delta^1_1$-$\mathsf{CA}_0$, *and weak* $\Sigma^1_1$-$\mathsf{AC}_0$ *all have the same minimum* (*i.e.*, *unique smallest*) $\omega$-*model, namely*

$$\mathrm{HYP} = \{X \subseteq \omega \colon X \text{ is hyperarithmetical}\}.$$

Our final task in this section is to show that $\mathsf{ATR}_0$ proves the existence of countable coded $\omega$-models of $\Sigma^1_1$-$\mathsf{AC}_0$, and indeed of $\Sigma^1_1$-$\mathsf{DC}_0$. Theorems VIII.4.8 and VIII.4.11 do not establish this result, since $\mathsf{ATR}_0$ is not strong enough to prove that $\mathrm{HYP}(X)$ is a countable coded $\omega$-model (remark VIII.4.4). Nevertheless, we shall see that $\mathrm{HYP}(X)$ can be characterized within $\mathsf{ATR}_0$ as the intersection of certain countable coded $\omega$-models (theorem VIII.4.23). In §VIII.6 we shall obtain a similar characterization of $\mathrm{HYP}(X)$ in terms of $\omega$-models of stronger theories.

LEMMA VIII.4.18. *The following is provable in* $\mathsf{ACA}_0$. *Let* $X$ *be such that* $\forall a\,(\mathcal{O}(a, X) \to \mathrm{H}^X_a$ *exists*). *Then there exist* $a^*$ *and* $M^*$ *such that*

(i) $\mathcal{O}_+(a^*, X)$ *and* $\neg\mathcal{O}(a^*, X)$,
(ii) $M^*$ *is a countable coded* $\omega$-*model of* $\mathsf{ACA}_0$,
(iii) $X \in M^*$, *and* $M^*$ *satisfies* $\mathcal{O}(a^*, X) \wedge \exists Y\, \mathrm{H}(a^*, X, Y)$.

PROOF. This is a variant of the proof of lemma VIII.3.24. Let $\mathcal{O}_1(a, X)$ be a $\Sigma^1_1$ formula which says: $\mathcal{O}_+(a, X)$ and there exists a countable coded $\omega$-model $M$ of $\mathsf{ACA}_0$ such that $X \in M$ and $M$ satisfies $\mathcal{O}(a, X) \wedge \exists Y\, \mathrm{H}(a, X, Y)$. We claim $\forall a\,(\mathcal{O}(a, X) \to \mathcal{O}_1(a, X))$. If $\mathcal{O}(a, X)$ holds, then by assumption $\mathrm{H}^X_a$ exists, and moreover the proof of theorem VIII.1.13 shows that there exists a countable coded $\omega$-model $M$ of $\mathsf{ACA}_0$ such that $\mathrm{H}^X_a \in M$. This implies $\mathcal{O}_1(a, X)$, thus proving our claim. From the claim plus lemma VIII.3.4, we see that $\exists a\,(\mathcal{O}_1(a, X) \wedge \neg\mathcal{O}(a, X))$. Letting $a^*$ be any such $a$, we obtain the desired conclusion. □

The next lemma may be viewed as a strong converse to lemma VIII.4.15.

LEMMA VIII.4.19. *The following is provable in* $\mathsf{ACA}_0$. *Let* $X$ *be such that* $\forall a\,(\mathcal{O}(a, X) \to \mathrm{H}^X_a$ *exists*). *Then there exists a countable coded* $\omega$-*model* $M$ *such that* $X \in M$ *and* $M$ *satisfies* $\Sigma^1_1$-$\mathsf{DC}_0$ (*hence also* $\Sigma^1_1$-$\mathsf{AC}_0$ *and* $\Delta^1_1$-$\mathsf{CA}_0$).

PROOF. We reason in $\mathsf{ACA}_0$. Let $X$, $a^*$ and $M^*$ be as in the previous lemma. Let $Y \in M^*$ be such that $\mathrm{H}(a^*, X, Y)$ holds. Thus $M^*$ satisfies $Y = \mathrm{H}^X_{a^*}$. For each $b \leq^X_{\mathcal{O}} a^*$, put

$$Y_b = \{(m, 0) \colon (m, 0) \in Y\} \cup \{(m, c + 1) \colon c <^X_{\mathcal{O}} b \wedge (m, c + 1) \in Y\}.$$

Thus $Y_{a^*} = Y$ and, for each $b \leq^X_{\mathcal{O}} a^*$, $M^*$ satisfies $Y_b = \mathrm{H}^X_b$. For each $b \leq^X_{\mathcal{O}} a^*$, put $M_b = \{Z \colon Z \leq_{\mathrm{T}} Y_b\}$.

Since $\neg\mathcal{O}(a^*, X)$ holds, there exists $I \subseteq \{b : b <^X_{\mathcal{O}} a^*\}$ such that

$$\forall b\, \forall c\, ((c <^X_{\mathcal{O}} b \wedge b \in I) \to c \in I)$$

and there is no $a \leq^X_{\mathcal{O}} a^*$ such that $I = \{b : b <^X_{\mathcal{O}} a\}$. Since $M^*$ satisfies $\mathcal{O}(a^*, X)$, we must have $I \notin M$, hence $I \neq \emptyset$ and

$$(\forall b \in I)\, (\exists c \in I) b <^X_{\mathcal{O}} c.$$

Put

$$M = \bigcup_{b \in I} M_b = \{Z : \exists b\, (b \in I \wedge Z \leq_{\mathrm{T}} Y_b)\}.$$

Clearly $X \in M$ and $M$ is a countable coded $\omega$-model of $\mathsf{ACA}_0$. It remains to show that $M$ satisfies $\Sigma^1_1$ dependent choice.

Suppose that $M$ satisfies $\forall n\, \forall U\, \exists V \eta(n, U, V)$ where $\eta(n, U, V)$ is a $\Sigma^1_1$ formula with parameters from $M$. Fix $b_0 \in I$ such that all of these parameters belong to $M_{b_0}$. Put $Z_0 = \emptyset$. Reasoning within $M^*$, choose a sequence of ordinal notations $b_n <^X_{\mathcal{O}} a^*$, $n \in \mathbb{N}$, and a sequence of sets $Z_n \in M_{b_n}$, as follows. We have already chosen $b_0$ and $Z_0$. Given $b_n$ and $Z_n$, let $b_{n+1}$ be the $<^X_{\mathcal{O}}$-least $b <^X_{\mathcal{O}} a^*$ such that $b_n <^X_{\mathcal{O}} b$ and $M_b$ satisfies $\exists V\, \eta(n, (Z_n)^n, V)$. Then pick $Z_{n+1} \in M_{b_{n+1}}$ such that $(Z_{n+1})^n = (Z_n)^n$ and $M^X_{b_{n+1}}$ satisfies $\eta(n, (Z_n)^n, (Z_{n+1})_n)$. Applying lemma VIII.3.10 inside $M^*$, we can choose $b_n$ and $Z_n$ so that the sequence $\langle b_n : n \in \mathbb{N}\rangle$ is recursive in $Y$.

By induction on $n$, it is clear that $\forall n\, (b_n \in I)$. Put

$$J = \{c : \exists n\, (c \leq^X_{\mathcal{O}} b_n)\}.$$

Then $J \subseteq I$. Moreover, since $J$ is arithmetical in $Y$, we have $J \in M^*$, hence $J \neq I$. Since $M^*$ satisfies $\mathcal{O}(a^*, X)$, there must exist $b^* \in I$ such that $J = \{c : c <^X_{\mathcal{O}} b^*\}$. Again applying lemma VIII.3.10 inside $M^*$, we see that the sequence $\langle Z_n : n \in \mathbb{N}\rangle$ is recursive in $Y_{b^*}$. Hence we can find $Z \in M_{b^*}$ such that $(Z)^n = (Z_n)^n$ for all $n$. Thus $Z \in M$, and $M$ satisfies $\forall n\, \eta(n, (Z)^n, (Z)_n)$.

This completes the proof of lemma VIII.4.19. □

THEOREM VIII.4.20. $\mathsf{ATR}_0$ *proves the existence of a countable coded* $\omega$*-model of* $\Sigma^1_1$-$\mathsf{DC}_0$ (*hence also of* $\Sigma^1_1$-$\mathsf{AC}_0$ *and* $\Delta^1_1$-$\mathsf{CA}_0$).

PROOF. This follows immediately from the previous lemma. □

COROLLARY VIII.4.21 (consistency of $\Sigma^1_1$-$\mathsf{AC}_0$, etc.). $\mathsf{ATR}_0$ *proves the consistency of* $\Sigma^1_1$-$\mathsf{DC}_0$ (*hence also of* $\Sigma^1_1$-$\mathsf{AC}_0$ *and* $\Delta^1_1$-$\mathsf{CA}_0$) *plus full induction*, $\Sigma^1_\infty$-$\mathsf{IND}$.

PROOF. This is like the proof of corollary VIII.1.14, using theorem VIII.4.20 instead of theorem VIII.1.13. □

COROLLARY VIII.4.22. *There exists a* $\Pi^0_1$ *sentence* $\psi$ *such that* $\psi$ *is provable in* $\mathsf{ATR}_0$ *but not in* $\Sigma^1_1$-$\mathsf{DC}_0$ (*hence also not in* $\Sigma^1_1$-$\mathsf{AC}_0$ *or* $\Delta^1_1$-$\mathsf{CA}_0$) *plus full induction*.

PROOF. Let $\psi$ be a sentence asserting the consistency of $\Sigma^1_1$-$\mathsf{DC}_0$ plus full induction. The result follows from Gödel's second incompleteness theorem [94, 115, 55, 222]. (Compare the proof of corollary VIII.1.8.) □

THEOREM VIII.4.23. *The following is provable in* $\mathsf{ATR}_0$. *Given* $W, X \subseteq \mathbb{N}$, *the following are pairwise equivalent*.

1. $W \in \mathrm{HYP}(X)$, *i.e.*, $W \leq_{\mathrm{H}} X$.
2. $W \in M$ *for all countable coded* $\omega$*-models* $M$ *such that* $X \in M$ *and* $M$ *satisfies weak* $\Sigma^1_1$-$\mathsf{AC}_0$.
3. *Same as* 2 *with weak* $\Sigma^1_1$-$\mathsf{AC}_0$ *replaced by* $\Delta^1_1$-$\mathsf{CA}_0$.
4. *Same as* 2 *with weak* $\Sigma^1_1$-$\mathsf{AC}_0$ *replaced by* $\Sigma^1_1$-$\mathsf{AC}_0$.
5. *Same as* 2 *with weak* $\Sigma^1_1$-$\mathsf{AC}_0$ *replaced by* $\Sigma^1_1$-$\mathsf{DC}_0$.

PROOF. The implication $1 \rightarrow 2$ follows from lemma VIII.4.15. The implications $2 \rightarrow 3$, $3 \rightarrow 4$, $4 \rightarrow 5$ are immediate since

$$\Sigma^1_1\text{-}\mathsf{DC}_0 \supseteq \Sigma^1_1\text{-}\mathsf{AC}_0 \supseteq \Delta^1_1\text{-}\mathsf{CA}_0 \supseteq \text{weak } \Sigma^1_1\text{-}\mathsf{AC}_0.$$

(See exercise VIII.4.14 and lemma VII.6.6.)

In order to prove $5 \rightarrow 1$, let $X$ and $W$ be such that $W \not\leq_{\mathrm{H}} X$. We must find a countable coded $\omega$-model $M$ of $\Sigma^1_1$-$\mathsf{DC}_0$ such that $X \in M$ and $W \notin M$. Let $M^*$, $a^*$ and $Y$ be as in the proof of lemma VIII.4.19. If $W \notin M^*$, the proof of lemma VIII.4.19 gives a countable coded $\omega$-model $M$ of $\Sigma^1_1$-$\mathsf{DC}_0$ such that $X \in M$ and $M \subseteq M^*$, hence $W \notin M$ and we are done.

Suppose now that $W \in M^*$. Put

$$K = \{b : b \leq^X_{\mathcal{O}} a^* \wedge W \not\leq_{\mathrm{T}} Y_b\}.$$

Then $K \in M^*$ (because $K$ is arithmetical in $X$, $Y$ and $W$). Since $W \not\leq_{\mathrm{H}} X$, we must have $\forall b\,((b <^X_{\mathcal{O}} a^* \wedge \mathcal{O}(b, X)) \rightarrow b \in K)$. But then, since $\neg\mathcal{O}(a^*, X)$ holds while $M^*$ satisfies $\mathcal{O}(a^*, X)$, there must exist $b^* \in K$ such that $\neg\mathcal{O}(b^*, X)$. We can then find $I$ as in the proof of theorem VIII.4.19 with the additional property that $I \subseteq \{b : b <^X_{\mathcal{O}} b^*\}$, hence $I \subseteq K$. Defining $M = \{Z : \exists b\,(Z \leq_{\mathrm{T}} Y_b \wedge b \in I)\}$ as in the proof of theorem VIII.4.19, we see that $M$ is a countable coded $\omega$-model of $\Sigma^1_1$-$\mathsf{DC}_0$ and $X \in M$ and $W \notin M$.

This completes the proof of theorem VIII.4.23. □

The following exercises provide an analog of theorem VIII.4.20 with $\mathsf{ATR}_0$ replaced by $\Pi^1_k$-$\mathsf{TR}_0$ for arbitrary $k$.

EXERCISES VIII.4.24. Fix $k$ such that $0 \leq k < \omega$.

1. Show that $\Pi^1_{k+1}$-$\mathsf{TR}_0$ proves the existence of a countable coded $\omega$-model of $\Sigma^1_{k+2}$-$\mathsf{DC}_0$, hence also of $\Sigma^1_{k+2}$-$\mathsf{AC}_0$ and of $\Delta^1_{k+2}$-$\mathsf{CA}_0$. (Hint: Imitate the proof of theorem VIII.4.20.)
2. Show that $\Delta^1_{k+2}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+2}$-$\mathsf{TI}_0$ implies the existence of a countable coded $\omega$-model of $\Sigma^1_{k+2}$-$\mathsf{DC}_0$, hence also of $\Sigma^1_{k+2}$-$\mathsf{AC}_0$ and of $\Delta^1_{k+2}$-$\mathsf{CA}_0$. (Hint: Use the previous exercise plus VII.7.12.1.)

The following exercise provides a strong converse for lemma VIII.4.7.

EXERCISE VIII.4.25. Show that $\mathsf{ATR}_0$ is equivalent over $\mathsf{RCA}_0$ to the scheme $\forall m\, \exists n\, \psi(m,n) \to \exists f\, \forall m\, \psi(m, f(m))$ where $\psi(m,n)$ is $\Pi^1_1$. (Hint: Use theorem V.5.1 and lemma VIII.4.7.)

**Notes for §VIII.4.** The fact that HYP is the minimum $\omega$-model of $\Delta^1_1$-$\mathsf{CA}_0$ is due to Kleene [145]. The analogous results for $\Sigma^1_1$-$\mathsf{CA}_0$ and $\Sigma^1_1$-$\mathsf{DC}_0$ are due to Kreisel [150] and Feferman; see also Harrison [106]. The fact that $\mathsf{ATR}_0$ proves the existence of a countable $\omega$-model of $\Sigma^1_1$-$\mathsf{DC}_0$, etc., is due to Friedman [62, chapter II], [64, 68, 69]. The results stated in exercises VIII.4.24 are probably new, but see Friedman [64]. In theorem VIII.4.11, Simpson [235] has shown that the hypothesis $\Sigma^1_1$-$\mathsf{IND}$ cannot be omitted.

In §VIII.5 we shall see that there exists a countable $\omega$-model of $\mathsf{ATR}_0$ (hence also of $\Sigma^1_1$-$\mathsf{AC}_0$) which does not satisfy $\Sigma^1_1$-$\mathsf{DC}_0$. This result is due to Friedman [62, chapter II]. Steel [257] has developed a technique known as tagged tree forcing and used it to show that there exists a countable $\omega$-model of $\Delta^1_1$-$\mathsf{CA}_0$ which does not satisfy $\Sigma^1_1$-$\mathsf{AC}_0$. Van Wesep [273, §I.1] has used tagged tree forcing to show that there exists a countable $\omega$-model of weak $\Sigma^1_1$-$\mathsf{AC}_0$ which does not satisfy $\Delta^1_1$-$\mathsf{CA}_0$.

## VIII.5. $\omega$-Model Reflection and Incompleteness

By *$\omega$-model reflection* we mean the principle that any true $\mathrm{L}_2$-sentence (possibly with set parameters) has a countable $\omega$-model. We formalize this in the following definition.

DEFINITION VIII.5.1 ($\omega$-model reflection). Let $\varphi(X_1, \ldots, X_k)$ be an $\mathrm{L}_2$-formula with no free variables other than $X_1, \ldots, X_k$. Then the formula

$$\forall X_1 \cdots \forall X_k\, [\varphi(X_1, \ldots, X_k) \to \exists \text{ countable coded } \omega\text{-model } M \text{ such that } X_1, \ldots, X_k \in M \text{ and } M \text{ satisfies } \mathsf{ACA}_0 \text{ plus } \varphi(X_1, \ldots, X_k)]$$

is an instance of the *$\omega$-model reflection scheme*. We define $\Sigma^1_\infty$-$\mathsf{RFN}_0$ to be the subsystem of $\mathsf{Z}_2$ whose axioms are those of $\mathsf{ACA}_0$ plus all instances of the $\omega$-model reflection scheme. Also, $\Sigma^1_k$-$\mathsf{RFN}_0$ consists of $\mathsf{ACA}_0$ plus all instances of $\omega$-model reflection in which the formula $\varphi(X_1, \ldots, X_k)$ is $\Sigma^1_k$.

Recall from §VII.2 that $\Pi^1_\infty$-$\mathsf{TI}_0$ consists of $\mathsf{ACA}_0$ plus the transfinite induction scheme. We shall prove the following theorem of Friedman: $\Sigma^1_\infty$-$\mathsf{RFN}_0$ is equivalent to $\Pi^1_\infty$-$\mathsf{TI}_0$. In other words, $\omega$-model reflection is equivalent to transfinite induction.

LEMMA VIII.5.2. *All instances of the $\omega$-model reflection scheme are provable in* $\Pi^1_\infty$-$\mathsf{TI}_0$.

Proof. Without loss, we may restrict our attention to instances of $\omega$-model reflection in which there is only one set parameter. Reasoning in $\mathsf{ACA}_0$, assume that we have a failure of $\omega$-model reflection, i.e., $\varphi(X_0)$ holds but there is no countable coded $\omega$-model $M$ such that $X_0 \in M$ and $M$ satisfies $\mathsf{ACA}_0$ plus $\varphi(X_0)$. Here $X_0$ is a fixed set, and $\varphi(X_0)$ is an $\mathrm{L}_2$-sentence which contains $X_0$ as a parameter. Since $\mathsf{ACA}_0$ is finitely axiomatizable (lemma VIII.1.5), we may assume that $\varphi(X_0)$ logically implies the axioms of $\mathsf{ACA}_0$.

Our proof will be based on a model-theoretic construction in the style of Henkin. The idea will be to construct a tree $T$ such that from any path through $T$ we can read off a countable coded $\omega$-model of $\varphi(X_0)$. The non-existence of such a model will imply that $T$ has no path, i.e., is well founded. On the other hand, the fact that $\varphi(X_0)$ is true will yield a failure of transfinite induction along the Kleene/Brouwer ordering of $T$.

We work with the language $\mathrm{L}_2(\underline{C})$ consisting of $\mathrm{L}_2$ plus countably many set constants $\underline{C}_j$, $j \in \mathbb{N}$. We assume that our language has been set up so that it contains no existential quantifiers. Form the $\mathrm{L}_2(\underline{C})$-sentence $\varphi(\underline{C}_0)$, and let $\langle \theta_i : i \in \mathbb{N} \rangle$ enumerate all $\mathrm{L}_2(\underline{C})$-sentences which are substitution instances of subformulas of $\varphi(\underline{C}_0)$. Let $\langle \eta_i(Y) : i \in \mathbb{N} \rangle$ and $\langle \psi_i(m) : i \in \mathbb{N} \rangle$ enumerate all $\mathrm{L}_2(\underline{C})$-formulas which are substitution instances of subformulas of $\varphi(\underline{C}_0)$ and have exactly one free variable, $Y$ or $m$ respectively. (Here of course $Y$ is a set variable and $m$ is a number variable.) We assume that our enumerations have been chosen so that $j \leq i$ whenever $\underline{C}_j$ occurs in $\theta_i$ or in $\eta_i(Y)$ or in $\psi_i(m)$.

For each $\tau \in \mathbb{N}^{<\mathbb{N}}$, let $S_\tau$ be the finite set of $\mathrm{L}_2(\underline{C})$-sentences consisting of $\varphi(\underline{C}_0)$ plus

$$\begin{array}{ll}
\theta_i & \text{if } 3i < \mathrm{lh}(\tau) \text{ and } \tau(3i) = 0, \\
\neg\theta_i & \text{if } 3i < \mathrm{lh}(\tau) \text{ and } \tau(3i) \neq 0, \\
\forall Y \eta_i(Y) & \text{if } 3i+1 < \mathrm{lh}(\tau) \text{ and } \tau(3i+1) = 0, \\
\neg\eta_i(\underline{C}_{i+1}) & \text{if } 3i+1 < \mathrm{lh}(\tau) \text{ and } \tau(3i+1) \neq 0, \\
\forall m\, \psi_i(m) & \text{if } 3i+2 < \mathrm{lh}(\tau) \text{ and } \tau(3i+2) = 0, \\
\neg\psi_i(\underline{n}) & \text{if } 3i+2 < \mathrm{lh}(\tau) \text{ and } \tau(3i+2) = n+1.
\end{array}$$

(Here $\underline{n}$ is a constant term denoting the number $n$.) The tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ is defined by putting $\tau$ into $T$ if and only if there is no "obvious inconsistency" in $S_\tau$. The "obvious inconsistencies" are of two kinds: (1) a propositional inconsistency; (2) a quantifier-free sentence which is false when $\underline{C}_0$ is interpreted as $X_0$.

If $f$ were a path through $T$, then there would exist a countable coded $\omega$-model $M$ such that $X_0 \in M$ and $M$ satisfies $\varphi(X_0)$, namely

$$M = \{(W)_i : i \in \mathbb{N}\}$$

where $n \in (W)_i$ if and only if the sentence $\underline{n} \in \underline{C}_i$ belongs to $\bigcup_{k\in\mathbb{N}} S_{f[k]}$. (See the formal definition of satisfaction for countable coded $\omega$-models, definition VII.2.1.) Since no such $\omega$-model exists, $T$ is well founded. Hence, by lemma V.1.3, the Kleene/Brouwer ordering $\mathrm{KB}(T)$ is a well ordering.

Let us say that $\tau \in T$ is *good* if there exists $W \subseteq \mathbb{N}$ such that the sentences in $S_\tau$ are all true when, for all $i$, $\underline{C}_i$ is interpreted as $(W)_i$. Since the sentences in question are all substitution instances of subformulas of a fixed sentence $\varphi(\underline{C}_0)$, the property of goodness is expressible by a single $\mathrm{L}_2$-formula (with $X_0$ appearing as a parameter). The empty sequence $\langle\rangle$ is good since $S_{\langle\rangle} = \{\varphi(\underline{C}_0)\}$ is true with $\underline{C}_0$ interpreted as $X_0$. It is also easy to see that if $\tau$ is good, then $\tau^\frown\langle k\rangle$ is good for some $k$. Hence there is no $\mathrm{KB}(T)$-least good $\tau \in T$. Thus we have a failure of transfinite induction along $\mathrm{KB}(T)$.

This completes the proof of lemma VIII.5.2. □

LEMMA VIII.5.3. *All instances of the transfinite induction scheme are provable in* $\Sigma^1_\infty$-$\mathsf{RFN}_0$.

PROOF. Let $\psi(j)$ be any $\mathrm{L}_2$-formula with a distinguished free number variable $j$. Reasoning in $\Sigma^1_\infty$-$\mathsf{RFN}_0$, we want to prove $\forall X\,(\mathrm{WO}(X) \to \mathrm{TI}(X,\psi))$. Assume $\mathrm{WO}(X) \wedge \neg\mathrm{TI}(X,\psi)$. By $\omega$-model reflection, let $M$ be a countable coded $\omega$-model such that $X \in M$ and $M$ satisfies $\neg\mathrm{TI}(X,\psi)$. By arithmetical comprehension using the code of $M$ as a parameter, let $Y$ be the set of all $j \in \mathbb{N}$ such that $M$ satisfies $\psi(j)$. Since $X$ is a well ordering, we have

$$\forall j\,(\forall i\,(i <_X j \to i \in Y) \to j \in Y) \to \forall j\,(j \in Y).$$

Hence $M$ satisfies $\mathrm{TI}(X,\psi)$, a contradiction. Lemma VIII.5.3 is proved. □

THEOREM VIII.5.4. $\Sigma^1_\infty$-$\mathsf{RFN}_0$ *is equivalent to* $\Pi^1_\infty$-$\mathsf{TI}_0$.

PROOF. Immediate from lemmas VIII.5.2 and VIII.5.3. □

COROLLARY VIII.5.5. $\Pi^1_\infty$-$\mathsf{CA}_0$ *proves all instances of* $\omega$*-model reflection.*

PROOF. This is immediate from lemma VIII.5.2, since obviously $\Pi^1_\infty$-$\mathsf{CA}_0$ proves all instances of transfinite induction. (In fact, $\Pi^1_k$-$\mathsf{CA}_0$ includes both $\Pi^1_k$-$\mathsf{TI}_0$ and $\Sigma^1_k$-$\mathsf{TI}_0$.) □

Our next theorem, also due to Friedman, is essentially an $\omega$-model version of Gödel's second incompleteness theorem. It will be seen to imply the existence of many countable $\omega$-models in which reflection fails.

THEOREM VIII.5.6 ($\omega$-model incompleteness). *Let $S$ be a recursive set of* $\mathrm{L}_2$*-sentences which includes the axioms of* $\mathsf{ACA}_0$. *If there exists a countable coded $\omega$-model of $S$, then there exists a countable coded $\omega$-model of*

(1) $S \cup \{\neg\exists$ countable coded $\omega$-model of $S\}$.

Proof. We are given a recursive set of $L_2$-sentences $S \supseteq \mathsf{ACA}_0$. Let $S^*$ be an $L_2$-theory consisting of $\mathsf{ACA}_0$ plus the assertion that our theorem fails for $S$. Formally, $S^*$ is the finitely axiomatizable $L_2$-theory consisting of $\mathsf{ACA}_0$ plus

(2) $\exists$ countable coded $\omega$-model of $S$, plus
(3) $\neg\exists$ countable coded $\omega$-model of (1).

We claim that $S^*$ proves its own consistency. To see this, we reason in $S^*$. By (2), let $M$ be a countable coded $\omega$-model of $S$. We shall show that $M$ satisfies $S^*$. By $\mathsf{ACA}_0$ and lemma VII.2.2, there exists a truth valuation for (2). Hence $M$ satisfies either (2) or its negation. In view of (3), $M$ does not satisfy (1), hence $M$ satisfies (2). Moreover, by another application of lemma VII.2.2, all countable coded $\omega$-models satisfy all true $\Pi^1_1$ sentences. In particular, since (3) is a true $\Pi^1_1$ sentence, $M$ satisfies (3). Thus $M$ is a countable coded $\omega$-model of $S^*$. Hence, by the soundness theorem, $S^*$ is consistent. This proves our claim.

Since $S^*$ proves its own consistency, it follows by Gödel's second incompleteness theorem [94, 115, 55, 222] that $S^*$ must be inconsistent. This means that $\mathsf{ACA}_0$ proves "if $S$ has a countable coded $\omega$-model, then so does (1)." Hence this statement is true. The proof of theorem VIII.5.6 is complete. □

Remark VIII.5.7. In the above proof, some care is needed as regards satisfaction and truth valuations. Note for instance that the theorem fails with $S = \mathsf{WKL}_0$, since every countable $\omega$-model of $\mathsf{WKL}_0$ contains a code for a countable $\omega$-model of $\mathsf{WKL}_0$ (see theorems VIII.2.2 and VIII.2.6 and remark VIII.2.14). Gödel's second incompleteness theorem is not violated because $\mathsf{WKL}_0$ is not strong enough to prove the existence of valuations (compare lemma VII.2.2).

Corollary VIII.5.8. *Let $S$ be a finite set of $L_2$-sentences. If there exists a countable $\omega$-model of $S$, then there exists a countable $\omega$-model of $S$ which does not satisfy $\Pi^1_\infty$-$\mathsf{TI}_0$.*

Proof. Put $S_1 = S \cup \mathsf{ACA}_0$. If $S_1$ has no countable $\omega$-model, there is nothing to prove. So assume that $S_1$ has a countable $\omega$-model. By theorem VIII.5.6, let $M$ be a countable $\omega$-model of

$$S_1 \cup \{\neg\exists \text{ countable coded } \omega\text{-model of } S_1\}.$$

Thus we have a failure of $\omega$-model reflection in $M$. Hence, by theorem VIII.5.4, there must be a failure of transfinite induction in $M$. This completes the proof. □

Remark VIII.5.9. The previous corollary provides a second proof that $\Pi^1_\infty$-$\mathsf{TI}_0$ is not finitely axiomatizable. Compare corollary VII.2.23 and remark VII.2.24.

COROLLARY VIII.5.10. *For each $k < \omega$, there exists a countable $\omega$-model of*

$$\Pi^1_k\text{-}\mathsf{CA}_0 \cup \{\neg\exists \text{ countable coded } \omega\text{-model of } \Pi^1_k\text{-}\mathsf{CA}_0\}.$$

*Such a model does not satisfy $\Pi^1_\infty$-$\mathsf{TI}_0$.*

PROOF. Immediate by theorems VIII.5.6 and VIII.5.4, since $\Pi^1_k$-$\mathsf{CA}_0$ is finitely axiomatizable. □

Theorem VIII.5.4 says that the general scheme of transfinite induction is equivalent to the general scheme of $\omega$-model reflection. It is natural to ask how much transfinite induction (as measured by formula complexity) is equivalent to how much $\omega$-model reflection. The next theorem gives a sharp result in one case. See also exercise VIII.5.15 below.

LEMMA VIII.5.11. *Over $\mathsf{ACA}_0$, $\Pi^1_1$ transfinite induction implies $\Sigma^1_1$ dependent choice.*

PROOF. We are trying to prove $\Sigma^1_1$ dependent choice, i.e.,

$$\forall i\, \forall X\, \exists Y\, \eta(i, X, Y) \to \exists Z\, \forall i\, \eta(i, (Z)^i, (Z)_i)$$

where $\eta(n, X, Y)$ is $\Sigma^1_1$. Using lemma V.1.4 (our normal form theorem for $\Sigma^1_1$ formulas), we can reduce this to

$$\forall i\, \forall f\, \exists g\, \forall n\, \theta(i, f[n], g[n]) \to \exists h\, \forall i\, \forall n\, \theta(i, (h)^i[n], (h)_i[n])$$

where $\theta(i, \tau_1, \tau_2)$ is arithmetical. Here of course $f$, $g$ and $h$ range over $\mathbb{N}^\mathbb{N}$, $(h)_i(m) = h((i, m))$, and $(h)^i(m) = h((j, k))$ if $m = (j, k)$ and $j < i$, $(h)^i(m) = 0$ otherwise.

Assume the hypothesis $\forall i\, \forall f\, \exists g\, \forall n\, \theta(i, f[n], g[n])$. To prove the conclusion, form a tree $T$ by putting $\tau \in T$ if and only if

$$(\forall i < \mathrm{lh}(\tau))\, (\forall n \leq \min\{\mathrm{lh}((\tau)^i), \mathrm{lh}((\tau)_i)\})\, \theta(i, (\tau)^i[n], (\tau)_i[n]).$$

Clearly $h$ is a path through $T$ if and only if $h$ satisfies the conclusion

$$\forall i\, \forall n\, \theta(i, (h)^i[n], (h)_i[n]).$$

Assume now that the conclusion fails, i.e., $T$ is well founded. Then, by lemma V.1.3, the Kleene/Brouwer ordering $\mathrm{KB}(T)$ is a well ordering. On the other hand, say that $\tau \in T$ is *good* if

$$\exists h\, (h[\mathrm{lh}(\tau)] = \tau \wedge (\forall i < \mathrm{lh}(\tau))\, \forall n\, \theta(i, (h)^i[n], (h)_i[n])).$$

Clearly the empty sequence $\langle\rangle$ is good. Moreover, the hypothesis

$$\forall i\, \forall f\, \exists g\, \forall n\, \theta(i, f[n], g[n])$$

implies that for each good $\tau$ there exists $m$ such that $\tau^\frown\langle m\rangle$ is good. Since the property of goodness is $\Sigma^1_1$, we have a failure of $\Pi^1_1$ transfinite induction along $\mathrm{KB}(T)$.

This completes the proof of lemma VIII.5.11. □

Theorem VIII.5.12. *The following are pairwise equivalent over* $\mathsf{ACA}_0$.

1. $\Pi^1_1$ *transfinite induction*.
2. $\Sigma^1_1$ *dependent choice*.
3. $\omega$*-model reflection for* $\Sigma^1_3$ *formulas*.

*In other words*, $\Pi^1_1$-$\mathsf{TI}_0 \equiv \Sigma^1_1$-$\mathsf{DC}_0 \equiv \Sigma^1_3$-$\mathsf{RFN}_0$.

Proof. The implication $1 \to 2$ is given by lemma VIII.5.11.

For $2 \to 3$, assume $\Sigma^1_1$ dependent choice, and let $\varphi(U_0)$ be a true $\Sigma^1_3$ sentence with a set parameter $U_0$. Write

$$\varphi(U_0) \equiv \exists V\, \forall X\, \exists Y\, \theta(U_0, V, X, Y)$$

where $\theta(U, V, X, Y)$ is arithmetical. Fix $U_1$ such that

$$\forall X\, \exists Y\, \theta(U_0, U_1, X, Y)$$

holds. Let $\pi(e, m_1, X_1)$ be a universal lightface $\Pi^0_1$ formula with exactly the displayed free variables (as in the proof of lemma VIII.1.5). By $\Sigma^1_1$ dependent choice, we can find $W$ such that $(W)_0 = U_0$, and $(W)_1 = U_1$, and

$$\forall i\, \theta(U_0, U_1, (W)_i, (W)_{2i+2}),$$

and

$$\forall m(\pi(e, m, (W)^i) \leftrightarrow m \in (W)_{2j+3})$$

for all $e$, $i$ and $j = (e, i)$. Letting $M = \{(W)_i : i \in \mathbb{N}\}$ be the countable $\omega$-model coded by $W$, we see that $M$ satisfies $\varphi(U_0)$ and $\mathsf{ACA}_0$. This proves $2 \to 3$.

It remains to prove $3 \to 1$. We proceed as in the proof of lemma VIII.5.3. Reasoning in $\Sigma^1_3$-$\mathsf{RFN}_0$, let $\psi(j)$ be $\Pi^1_1$ and assume $\mathrm{WO}(X) \wedge \neg \mathrm{TI}(X, \psi)$. Since $\neg \mathrm{TI}(X, \psi)$ is equivalent to a $\Sigma^1_3$ formula, we can apply reflection to obtain a countable coded $\omega$-model $M$ such that $X \in M$ and $M$ satisfies $\neg \mathrm{TI}(X, \psi)$. By arithmetical comprehension, let $Y$ be the set of $j$ such that $M$ satisfies $\psi(j)$. Then $Y$ witnesses the failure of $\mathrm{WO}(X)$, a contradiction.

This completes the proof of theorem VIII.5.12. □

As an application of theorems VIII.5.6 and VIII.5.12, we present the following independence results, due to Friedman.

Theorem VIII.5.13. *There exists a countable* $\omega$*-model of* $\mathsf{ATR}_0$ *which does not satisfy* $\Sigma^1_1$ *dependent choice*.

Proof. By theorem VIII.5.6, let $M$ be a countable $\omega$-model of

$$\mathsf{ATR}_0 \cup \{\neg\exists \text{ countable coded } \omega\text{-model of } \mathsf{ATR}_0\}.$$

Let $\varphi$ be the $\Pi^1_2$ sentence $\forall X\, \forall a\, (\mathcal{O}(a, X) \to \exists Y\, \mathrm{H}(a, X, Y))$. By theorem VIII.3.15 we see that $M$ satisfies $\varphi \wedge \neg\exists$ countable coded $\omega$-model of $\mathsf{ACA}_0$ plus $\varphi$. Thus $\omega$-model reflection for $\varphi$ fails in $M$. Hence, by the implication $2 \to 3$ in theorem VIII.5.12, $\Sigma^1_1$ dependent choice fails in $M$. This completes the proof. □

COROLLARY VIII.5.14. *There exists a countable $\omega$-model of $\Sigma^1_1$-$\mathsf{AC}_0$ which does not satisfy $\Sigma^1_1$-$\mathsf{DC}_0$.*

PROOF. This is immediate from theorem VIII.5.13 in view of the fact that $\mathsf{ATR}_0$ includes $\Sigma^1_1$-$\mathsf{AC}_0$ (lemma VIII.4.1). □

EXERCISE VIII.5.15. Show that, for each $k < \omega$, $\Pi^1_{k+1}$ transfinite induction is equivalent to $\omega$-model reflection for $\Sigma^1_{k+3}$ formulas, over $\mathsf{ACA}_0$. This generalizes the equivalence $1 \leftrightarrow 3$ of theorem VIII.5.12.

**Notes for §VIII.5.** Theorem VIII.5.4 has been announced by Friedman [68]. The $\omega$-model incompleteness theorem VIII.5.6 and corollaries VIII.5.8 and VIII.5.10 are due to Friedman [62, chapter II], [68]. Steel [255] has given a purely recursion-theoretic proof of theorem VIII.5.6, not using Gödel's second incompleteness theorem. See also Friedman [70]. Lemma VIII.5.11 and theorem VIII.5.12 are due to Simpson [235]; see also Sy Friedman [81]. Theorem VIII.5.13 and corollary VIII.5.14 are due to Friedman [62, chapter II]. The result of exercise VIII.5.15 is due to Jäger/Strahm [129].

## VIII.6. $\omega$-Models of Strong Systems

In this section we shall prove that, for any countable model $M$ of $\mathsf{ATR}_0$, $\mathrm{HYP}^M$ is the intersection of all $\beta$-submodels of $M$ (corollary VIII.6.10). In addition, we shall prove the following results concerning an arbitrary, recursively axiomatizable theory $S$ in the language of $\mathrm{L}_2$. If $S$ includes weak $\Sigma^1_1$-$\mathsf{AC}_0$ and has a countable $\omega$-model, then HYP is the intersection of all countable $\omega$-models of $S$ (theorem VIII.6.6). If in addition $S$ includes $\mathsf{ATR}_0$, then for any countable $\omega$-model $M$ of $S$, $\mathrm{HYP}^M$ is the intersection of all $\omega$-submodels of $M$ which satisfy $S$ (theorem VIII.6.12, exercise VIII.6.23).

DEFINITION VIII.6.1 (essentially $\Sigma^1_1$ formulas). The class of *essentially $\Sigma^1_1$ formulas* is the smallest class of $\mathrm{L}_2$-formulas which contains all arithmetical formulas and is closed under conjunction, disjunction, universal number quantification, existential number quantification, and existential set quantification.

LEMMA VIII.6.2. *For any essentially $\Sigma^1_1$ formula $\varphi$, we can find a $\Sigma^1_1$ formula $\varphi'$ with the same free variables, such that*

(i) *$\Sigma^1_1$-$\mathsf{AC}_0$ proves $\varphi \to \varphi'$,*
(ii) *$\mathsf{ACA}_0$ proves $\varphi' \to \varphi$.*

(See also lemma VIII.3.21.)

PROOF. By induction on $\varphi$. The most interesting case is when $\varphi$ is of the form $\forall n\, \psi(n)$. By inductive hypothesis, find a $\Sigma^1_1$ formula $\psi'(n)$

such that $\Sigma^1_1$-AC$_0$ proves $\psi(n) \to \psi'(n)$ and ACA$_0$ proves $\psi'(n) \to \psi(n)$. Write $\psi'(n) \equiv \exists X\, \theta'(n, X)$ where $\theta'(n, X)$ is arithmetical, and put $\varphi' \equiv \exists Y\, \forall n\, \theta'(n, (Y)_n)$, where $Y$ is a new set variable. Clearly $\Sigma^1_1$-AC$_0$ proves $\varphi \to \varphi'$ and ACA$_0$ proves $\varphi' \to \varphi$. □

The following lemma expresses a simple instance of $\omega$-model reflection (compare §VIII.5).

LEMMA VIII.6.3. *Let $\varphi(X_1, \ldots, X_k)$ be an essentially $\Sigma^1_1$ formula with no free set variables other than $X_1, \ldots, X_k$. Then* ATR$_0$ *proves*

$$\forall X_1 \cdots \forall X_k\, [\varphi(X_1, \ldots, X_k) \to \exists \text{ countable coded } \omega\text{-model } M \text{ such that } X_1, \ldots, X_k \in M \text{ and } M \text{ satisfies ACA}_0 \text{ plus } \varphi(X_1, \ldots, X_k)].$$

PROOF. Given $\varphi(X_1, \ldots, X_k)$, let $\varphi'(X_1, \ldots, X_k)$ be a $\Sigma^1_1$ formula as in the previous lemma. Write

$$\varphi'(X_1, \ldots, X_k) \equiv \exists Y\, \theta'(X_1, \ldots, X_k, Y)$$

where $\theta'$ is arithmetical. Reasoning in ATR$_0$, let $X_1, \ldots, X_k$ be such that $\varphi(X_1, \ldots, X_k)$ holds. By lemma VIII.4.1 we have $\Sigma^1_1$-AC$_0$, hence $\varphi'(X_1, \ldots, X_k)$ holds. Let $Y$ be such that $\theta'(X_1, \ldots, X_k, Y)$ holds. By theorem VIII.1.13, let $M$ be a countable coded $\omega$-model of ACA$_0$ such that $X_1, \ldots, X_k, Y \in M$. Then $M$ satisfies $\varphi'(X_1, \ldots, X_k)$. Hence $M$ satisfies $\varphi(X_1, \ldots, X_k)$. Our lemma is proved. □

Recall that, for $Y \subseteq \mathbb{N}$, $(Y)_i = \{m : (m, i) \in Y\}$.

LEMMA VIII.6.4 (GKT theorem in ATR$_0$). *The following is provable in* ATR$_0$. *Let $X$ and $Y$ be such that $\forall i\, ((Y)_i \not\leq_{\mathrm{H}} X)$. Let $\varphi(W, X)$ be a $\Sigma^1_1$ formula with no free set variables other than $W$ and $X$. If $\exists W\, \varphi(W, X)$, then*

$$\exists W\, (\varphi(W, X) \wedge \forall i\, \forall j\, ((Y)_i \neq (W)_j))).$$

(Compare lemma VIII.2.23.)

PROOF. We use $f$ as a function variable ranging over $\mathbb{N}^{\mathbb{N}}$. As usual, we identify $W \subseteq \mathbb{N}$ with its characteristic function, $W(m) = 1$ if $m \in W$, $0$ if $m \notin W$. By lemma V.1.4 (our formalized version of the Kleene normal form theorem), we can find an arithmetical formula $\theta(\sigma, \tau, X)$ with no free set or function variables other than $X$, such that ACA$_0$ proves

$$\varphi(W, X) \leftrightarrow \exists f\, \forall n\, \theta(W[n], f[n], X).$$

Let $\theta^*(\sigma, \tau, X)$ be the $\Sigma^1_1$ formula

$$\exists W\, \exists f\, (W[\mathrm{lh}(\sigma)] = \sigma \wedge f[\mathrm{lh}(\tau)] = \tau \wedge \forall n\, \theta(W[n], f[n], X)).$$

Reasoning in ATR$_0$, assume the hypotheses of our lemma. Note that the following true statements are expressible by essentially $\Sigma^1_1$ formulas: $\forall a(\mathcal{O}(a, X) \to H^X_a$ exists); $\forall i((Y)_i \not\leq_{\mathrm{H}} X)$; and $\exists W \varphi(W, X)$. Hence, by

lemma VIII.6.3, there exists a countable coded $\omega$-model $M$ of $\mathsf{ACA}_0$ such that $X, Y \in M$ and these statements are true in $M$.

Clearly $M$ satisfies $\theta^*(\langle\rangle, \langle\rangle, X)$. We claim that if $M$ satisfies $\theta^*(\sigma, \tau, X)$, then for all $i$ and $j$ there exists $\sigma' \supseteq \sigma$ such that $M$ satisfies $\theta^*(\sigma', \tau, X)$ and $(Y)_i[\mathrm{lh}((\sigma')_j)] \neq (\sigma')_j$. If this were not so, then for all $m \in \mathbb{N}$ and $k \in \{0, 1\}$, we would have

$$(Y)_i(m) = k \leftrightarrow M \text{ satisfies } (\exists \sigma' \supseteq \sigma)\,(\theta^*(\sigma', \tau, X) \wedge (\sigma')_j(m) = k)).$$

Thus $M$ would satisfy that $(Y)_i$ is $\Delta^1_1$ in $X$. Hence by theorem VIII.3.19, $M$ would satisfy $(Y)_i \leq_{\mathrm{H}} X$. This contradiction proves the claim.

Now standing outside $M$ and applying the claim repeatedly, we can find sequences $\sigma_0 \subseteq \sigma_1 \subseteq \cdots \subseteq \sigma_k \subseteq \cdots$ and $\tau_0 \subseteq \tau_1 \subseteq \cdots \subseteq \tau_k \subseteq \cdots$ such that, for all $k$, $\mathrm{lh}(\sigma_k) = \mathrm{lh}(\tau_k) \geq k$ and $M$ satisfies $\theta^*(\sigma_k, \tau_k, X)$ and, if $k = (i, j)$, $(Y)_i[\mathrm{lh}((\sigma_k)_j)] \neq (\sigma_k)_j$. (These sequences are recursive in the satisfaction function of $M$.) Putting $W = \bigcup_k \sigma_k$ and $f = \bigcup_k \tau_k$, we get $\forall n\, \theta(W[n], f[n], X)$ and $\forall i \forall j\, (Y)_i \neq (W)_j$. This completes the proof of lemma VIII.6.4. □

THEOREM VIII.6.5. *The following is provable in* $\mathsf{ATR}_0$. *Let $S$ be an $X$-recursive set of* $\mathrm{L}_2$*-sentences. Suppose there exists a countable coded $\omega$-model $M$ such that $X \in M$ and $M$ satisfies $S$. Given $Y$ such that $\forall i\, ((Y)_i \not\leq_{\mathrm{H}} X)$, there exists a countable coded $\omega$-model $M$ such that $X \in M$ and $\forall i\, ((Y)_i \notin M)$ and $M$ satisfies $S$.*

PROOF. Let $\varphi(W, X)$ be a $\Sigma^1_1$ formula which says that $(W)_0 = X$ and $W$ is a code for a countable $\omega$-model of $S$. Applying lemma VIII.6.4, we obtain $W$ such that $\varphi(W, X)$ holds and $\forall i \forall j\, (Y)_i \neq (W)_j$. We complete the proof by letting $M = \{(W)_j : j \in \mathbb{N}\}$ be the countable $\omega$-model which is coded by $W$. □

The following corollary is sometimes described by saying that HYP is the "hard core" of $\omega$-models of $S$.

COROLLARY VIII.6.6 (intersection of $\omega$-models). *Let $S$ be a recursive set of* $\mathrm{L}_2$*-sentences which includes the axioms of weak* $\Sigma^1_1$-$\mathsf{AC}_0$. *If $S$ has a countable $\omega$-model, then*

$$\mathrm{HYP} = \bigcap \{M : M \text{ is a countable } \omega\text{-model of } S\}.$$

PROOF. By lemma VIII.4.15, HYP is included in all $\omega$-models of weak $\Sigma^1_1$-$\mathsf{AC}_0$. Hence HYP is included in the intersection of all $\omega$-models of $S$. Now let $M_1$ be some countable $\omega$-model of $S$ and let $\langle Y_i : i \in \mathbb{N}\rangle$ be an enumeration of the sets in $M_1$ which are not in HYP. By theorem VIII.6.5 there exists a countable $\omega$-model $M_2$ of $S$ such that $\forall i\, (Y_i \notin M_2)$. Thus $\mathrm{HYP} = M_1 \cap M_2$. This gives our corollary. □

The next theorem is essentially a reformulation of theorem VIII.6.5. It differs from theorem VIII.6.5 in that it does not mention $\omega$-models.

THEOREM VIII.6.7. *The following is provable in* $\mathsf{ATR}_0$. *Let* $X$ *and* $Y$ *be such that* $\forall i\,((Y)_i \not\leq_{\mathrm{H}} X)$. *Let* $\varphi(X, Z)$ *be a* $\Sigma^1_1$ *formula with no free set variables other than* $X$ *and* $Z$. *If* $\exists Z\,\varphi(X, Z)$, *then* $\exists Z\,(\varphi(X, Z) \wedge \forall i\,((Y)_i \not\leq_{\mathrm{H}} X \oplus Z))$.

PROOF. Assume the hypotheses. By lemma VIII.6.3, there exists a countable coded $\omega$-model $M$ of $\mathsf{ACA}_0$ such that $X \in M$ and $M$ satisfies

$$\exists Z\,(\varphi(X, Z) \wedge \forall a\,(\mathcal{O}(a, X \oplus Z) \to \mathrm{H}_a^{X\oplus Z} \text{ exists})).$$

By theorem VIII.6.5, there exists $M$ as above with the additional property that $\forall i\,((Y)_i \notin M)$. Letting $Z \in M$ be as above, we clearly have $\varphi(X, Z)$ and $\forall W\,(W \leq_{\mathrm{H}} X \oplus Z \to W \in M)$, hence $\forall i\,((Y)_i \not\leq_{\mathrm{H}} X \oplus Z)$. This completes the proof. □

The next theorem and its corollaries concern $\beta$-models rather than $\omega$-models and are therefore somewhat out of place in this chapter. Our reason for presenting them here is that they constitute a significant application of theorem VIII.6.7.

Recall from §VII.1 that a *$\beta$-submodel* of $M$, $M' \subseteq_\beta M$, is defined to be a submodel of $M$ with the same integers, $M' \subseteq_\omega M$, such that for any $\Sigma^1_1$ sentence $\chi$ with parameters from $M'$, $M' \models \chi$ if and only if $M \models \chi$.

THEOREM VIII.6.8. *Let* $M$ *be any countable model of* $\mathsf{ATR}_0$. *Let* $X, Y \in M$ *be such that* $M$ *satisfies* $\forall i\,((Y)_i \not\leq_{\mathrm{H}} X)$. *Then there exists a model* $M' \subseteq_\beta M$ *such that* $X \in M'$ *and* $\forall i\,((Y)_i \notin M')$. *Such an* $M'$ *is again a model of* $\mathsf{ATR}_0$.

PROOF. Let $\varphi(e, X, Z)$ be a universal $\Sigma^1_1$ formula with only the free variables shown. Let $\{e_n : n \in \mathbb{N}\}$ be an enumeration of the integers of the countable model $M$ (which need not be an $\omega$-model).

Fix $X, Y \in M$ such that $M$ satisfies $\forall i\,((Y)_i \not\leq_{\mathrm{H}} X)$. Since $M$ is a model of $\mathsf{ATR}_0$, we can apply theorem VIII.6.7 repeatedly within $M$ to obtain a sequence of sets $Z_0, Z_1, \ldots, Z_n, \ldots \in M$ such that

(i) $Z_0 = X$;
(ii) for all $n$, $M$ satisfies $\forall i\,((Y)_i \not\leq_{\mathrm{H}} Z_0 \oplus \cdots \oplus Z_n)$;
(iii) if $M$ satisfies $\exists Z\,\varphi(e_n, Z_0 \oplus \cdots \oplus Z_n, Z)$, then $Z_{n+1}$ is such a $Z$.

Let $M'$ be the $\omega$-submodel of $M$ consisting of $\{Z_n : n \in \mathbb{N}\}$. By construction, $M'$ is a $\beta$-submodel of $M$. Since $\mathsf{ATR}_0$ consists of $\mathsf{ACA}_0$ plus some $\Pi^1_2$ axioms, any $\beta$-submodel of a model of $\mathsf{ATR}_0$ is again a model of $\mathsf{ATR}_0$. In particular $M'$ is a model of $\mathsf{ATR}_0$. This completes the proof. □

COROLLARY VIII.6.9 (proper $\beta$-submodels). *If* $M$ *is any countable model of* $\mathsf{ATR}_0$, *then* $M$ *has a proper* $\beta$*-submodel* $M' \subseteq_\beta M$, $M' \neq M$. *Any such submodel is again a model of* $\mathsf{ATR}_0$.

PROOF. Let $Y \in M$ be such that $M \models Y$ is not hyperarithmetical. (The existence of such a $Y$ is implicit in the results of §§VIII.3 and VIII.4. See for example theorem VIII.3.15 and lemmas VIII.3.24 and VIII.3.25.) By theorem VIII.6.8, there exists $M' \subseteq_\beta M$ such that $Y \notin M$. □

COROLLARY VIII.6.10 (intersection of $\beta$-submodels). *If $M$ is any countable model of $\mathsf{ATR}_0$, then*

$$\mathrm{HYP}^M = \{Y : M \models Y \text{ is hyperarithmetical}\}$$

*can be characterized as the intersection of all $\beta$-submodels of $M$.*

COROLLARY VIII.6.11 (intersection of $\beta$-models). HYP *is the intersection of all $\beta$-models.*

The rest of this section is concerned with the following theorem of Quinsey.

THEOREM VIII.6.12 (proper $\omega$-submodels). *Let $S$ be a recursive set of $L_2$-sentences which includes the axioms of $\mathsf{ATR}_0$. Let $M$ be a countable $\omega$-model of $S$. Then $M$ has a proper $\omega$-submodel $M' \subseteq_\omega M$, $M' \neq M$, such that $M'$ is again an $\omega$-model of $S$.*

As interesting special cases of Quinsey's theorem VIII.6.12, we mention the following corollaries.

COROLLARY VIII.6.13. *For $1 \leq k < \omega$, any countable $\omega$-model $M$ of $\Pi^1_k$-$\mathsf{CA}_0$ has a proper $\omega$-submodel $M' \subseteq_\omega M, M' \neq M$, such that $M'$ is again an $\omega$-model of $\Pi^1_k$-$\mathsf{CA}_0$.*

COROLLARY VIII.6.14. *Any countable $\omega$-model $M$ of $\Pi^1_\infty$-$\mathsf{CA}_0$ has a proper $\omega$-submodel $M' \subseteq_\omega M, M' \neq M$, such that $M'$ is again an $\omega$-model of $\Pi^1_\infty$-$\mathsf{CA}_0$.*

Before beginning the proof of theorem VIII.6.12, we present a couple of preliminary lemmas.

LEMMA VIII.6.15. *The scheme of $\Sigma^1_1$ transfinite induction (see definition* VII.2.14*) is provable in $\mathsf{ATR}_0$ plus $\Sigma^1_1$-$\mathsf{IND}$. Hence $\Sigma^1_1$ transfinite induction holds in any $\omega$-model of $\mathsf{ATR}_0$.*

PROOF. We reason within $\mathsf{ATR}_0$ plus $\Sigma^1_1$ induction. Let $X$ be a countable linear ordering on which $\Sigma^1_1$ transfinite induction fails, i.e.,

$$\forall j\, (\forall i\, (i <_X j \to \varphi(i)) \to \varphi(j))$$

but $\neg\forall j\, \varphi(j)$. Here $\varphi(j)$ is a $\Sigma^1_1$ formula with a distinguished free number variable $j$. Put $\psi(j) \equiv \neg\varphi(j)$. Then we have $\exists j\, \psi(j)$ and

$$\forall j\, (\psi(j) \to \exists i\, (i <_X j \wedge \psi(i))).$$

By lemma VIII.4.10, there exists $f : \mathbb{N} \to \mathbb{N}$ such that

$$\forall n\, (\psi(f(n)) \wedge f(n+1) <_X f(n)).$$

Hence $X$ is not a well ordering. This proves the first sentence of the lemma. The second sentence follows since any $\omega$-model automatically satisfies full induction. □

The next lemma is a variant of the "pseudohierarchy principle" of §V.4. Recall definition V.1.1 according to which $\mathrm{WO}(X)$ means that $X$ is a countable well ordering.

LEMMA VIII.6.16. *Let $M$ be a countable $\omega$-model of $\mathsf{ATR}_0$ which is not a $\beta$-model. Let $\varphi(X)$ be a $\Sigma^1_1$ formula with parameters from $M$ and no free variables other than $X$. If*

$$\forall X\,((\mathrm{WO}(X) \wedge X \in M) \rightarrow M \text{ satisfies } \varphi(X)),$$

*then*

$$\exists X\,(\neg\mathrm{WO}(X) \wedge X \in M \wedge M \text{ satisfies } (\mathrm{WO}(X) \wedge \varphi(X))).$$

PROOF. We first claim that we can find $Y \in M$ such that $\neg\mathrm{WO}(Y)$ and $M \models \mathrm{WO}(Y)$. To see this, let $\chi$ be a $\Sigma^1_1$ sentence with parameters in $M$ such that $\chi$ is true but $M \models \neg\chi$. By the Kleene normal form theorem (lemma V.1.4), we can find an arithmetical formula $\theta(\tau)$ such that $\mathsf{ACA}_0$ proves $\chi \leftrightarrow \exists f\,\forall m\,\theta(f[m])$. Let $T$ consist of all $\tau \in \mathbb{N}^{<\mathbb{N}}$ such that $(\forall m \leq \mathrm{lh}(\tau))\,\theta(\tau[m])$ holds. Then $T$ is a tree, $T$ has a path, $T \in M$, and $M \models T$ has no path. Putting $Y = \mathrm{KB}(T)$, we see by lemma V.1.3 that $Y \in M$, $\neg\mathrm{WO}(Y)$, and $M \models \mathrm{WO}(Y)$. This proves our claim.

For each $i \in \mathrm{field}(Y)$, let $Y_i$ be the initial segment of $Y$ determined by $i$, i.e., $k \leq_{Y_i} j \leftrightarrow k \leq_Y j <_Y i$. The hypothesis of our lemma implies $\forall i\,(\mathrm{WO}(Y_i) \rightarrow M \models \varphi(Y_i))$. On the other hand, since $\neg\forall i\,\mathrm{WO}(Y_i)$, it cannot be the case that $\forall i\,(\mathrm{WO}(Y_i) \leftrightarrow M \models \varphi(Y_i))$. Otherwise we would have

$$M \models \forall j\,(\forall i\,(i <_Y j \rightarrow \varphi(Y_i)) \rightarrow \varphi(Y_j)) \wedge \neg\forall i\,\varphi(Y_i)$$

contradicting the fact that $M \models \Sigma^1_1$ transfinite induction (lemma VIII.6.15). Hence there exists $k$ such that $\neg\mathrm{WO}(Y_k)$ and $M \models \varphi(Y_k)$. Putting $X = Y_k$ for any such $k$, we obtain the desired conclusions.

This completes the proof of lemma VIII.6.16. □

The proof of theorem VIII.6.12 will be based on the notion of *fulfillment*, defined below.

DEFINITION VIII.6.17 (prenex formulas). An $\mathrm{L}_2$-formula is *prenex* if it is of the form

$$\forall X_1\,\exists Y_1 \cdots \forall X_k\,\exists Y_k\,\theta(X_1, \ldots, X_k, Y_1, \ldots, Y_k) \tag{23}$$

where $\theta$ is arithmetical.

A *finite $\omega$-model* is a finite, nonempty collection of subsets of $\mathbb{N}$.

DEFINITION VIII.6.18 (fulfillment). Let $\varphi$ be a prenex $\mathrm{L}_2$-sentence of the form (23). Let $\langle M_0, M_1, \ldots, M_l\rangle$ be a finite sequence of finite $\omega$-models. We say that $\langle M_0, M_1, \ldots, M_l\rangle$ *fulfills* $\varphi$ if $M_0 \subseteq M_1 \subseteq \cdots \subseteq M_l$ and

$$\forall i_1\,(\forall X_1 \in M_{i_1})\,(\exists Y_1 \in M_{i_1+1})\,(\forall i_2 \geq i_1)\,(\forall X_2 \in M_{i_2})\,(\exists Y_2 \in M_{i_2+1}) \cdots$$
$$(\forall i_k \geq i_{k-1})\,(\forall X_k \in M_{i_k})\,(\exists Y_k \in M_{i_k+1})\,\theta(X_1, X_2, \ldots, X_k, Y_1, Y_2, \ldots, Y_k)$$

where $i_1, i_2, \ldots, i_k$ range over $\{0, 1, \ldots, l-1\}$.

The motivation for the concept of fulfillment is explained by the following example.

EXAMPLE VIII.6.19. Let $M$ be a countable $\omega$-model of an $L_2$-sentence $\varphi$. We may assume that $\varphi$ is prenex of the form (23). Let

$$f_1 : M \to M, f_2 : M^2 \to M, \ldots, f_k : M^k \to M$$

be a set of *Skolem functions for* $\varphi$, i.e., we have

$$\theta(X_1, X_2, \ldots, X_k, f_1(X_1), f_2(X_1, X_2), \ldots, f_k(X_1, X_2, \ldots, X_k))$$

for all $X_1, X_2, \ldots, X_k \in M$. Let $\langle M_0, M_1, \ldots, M_l \rangle$ be a finite sequence of finite $\omega$-models such that

$$M_i \cup f_1(M_i) \cup f_2(M_i^2) \cup \cdots \cup f_k(M_i^k) \subseteq M_{i+1}$$

for all $i < l$. Then $\langle M_0, M_1, \ldots, M_l \rangle$ fulfills $\varphi$. (This is easily proved.)

In light of the above example, the following lemma should be plausible.

LEMMA VIII.6.20. *Let* $\langle M_i : i \in \mathbb{N} \rangle$ *be an infinite sequence of finite* $\omega$*-models such that, for all* $l$, $\langle M_0, M_1, \ldots, M_l \rangle$ *fulfills* $\varphi$. *Then the countable* $\omega$*-model* $M = \bigcup_{i \in \mathbb{N}} M_i$ *satisfies* $\varphi$.

PROOF. Straightforward. □

DEFINITION VIII.6.21 (fulfillment tree). Let $S = \{\varphi_i : i \in \mathbb{N}\}$ be a set of $L_2$-sentences. We may assume that each $\varphi_i$ is prenex. A *fulfillment tree for* $S$ consists of a tree $T \subseteq \mathbb{N}^{<\mathbb{N}}$ together with a $T$-indexed collection of finite $\omega$-models $\langle M_\tau : \tau \in T \rangle$ such that, for all $\tau \in T$ and $i \leq \mathrm{lh}(\tau)$, $\langle M_{\tau[i]}, M_{\tau[i+1]}, \ldots, M_\tau \rangle$ fulfills $\varphi_i$.

LEMMA VIII.6.22. *Let* $S$ *be a recursive set of prenex* $L_2$*-sentences. Let* $M$ *be a countable* $\omega$*-model of* $S$ *plus* $\Sigma^1_1$ *choice,* $\Sigma^1_1$-$\mathsf{AC}_0$. *For all countable well orderings* $X$ *such that* $X \in M$, $M$ *contains a fulfillment tree* $\langle M_\tau : \tau \in T \rangle$ *for* $S$ *such that* $|\mathrm{KB}(T)| = |X|$.

PROOF. This lemma will be proved by transfinite induction on the countable ordinal number $|X|$. In order to keep the induction going, we shall prove a stronger statement.

Let $S = \{\varphi_i : i \in \mathbb{N}\}$. We may assume without loss that each $\varphi_i$ is prenex. For each $\varphi_i$ choose a set of Skolem functions

$$f_{i1} : M \to M, f_{i2} : M^2 \to M, \ldots, f_{ik_i} : M^{k_i} \to M$$

as in example VIII.6.19. A finite sequence of finite $\omega$-models $\langle M_0, M_1, \ldots, M_l \rangle$ is said to *strongly fulfill* $\varphi_i$ if $\langle M_0, M_1, \ldots, M_l \rangle \in M$ and

$$M_j \cup f_{i1}(M_j) \cup f_{i2}(M_j^2) \cup \cdots \cup f_{ik_i}(M_j^{k_i}) \subseteq M_{j+1}$$

for all $j < l$. We say that $\langle M_0, M_1, \ldots, M_l \rangle$ *strongly fulfills* $S$ if it strongly fulfills $\varphi_i$ for all $i \leq l$. It is clear that for any $l \in \mathbb{N}$ there exists $\langle M_0, M_1, \ldots, M_l \rangle$ which strongly fulfills $S$. Moreover, if $\langle M_0, M_1, \ldots, M_l \rangle$

strongly fulfills $S$, then there exists $M_{l+1}$ such that $\langle M_0, M_1, \ldots, M_l, M_{l+1}\rangle$ strongly fulfills $S$.

A fulfillment tree $\langle M'_\tau : \tau \in T\rangle$ is said to *begin with*

$$\langle M_0, M_1, \ldots, M_l\rangle$$

if there is exactly one $\tau \in T$ of length $l$, and for this $\tau$ we have $M'_{\tau[i]} = M_i$ for all $i \leq l$.

Now let $X$ be a countable well ordering such that $X \in M$, and suppose that $\langle M_0, M_1, \ldots, M_l\rangle$ strongly fulfills $S$. We claim that $M$ contains a fulfillment tree $\langle M'_\tau : \tau \in T\rangle$ for $S$ beginning with $\langle M_0, M_1, \ldots, M_l\rangle$ such that

$$|\mathrm{KB}(T)| = |X| + l.$$

This claim will be proved by induction on the countable ordinal $|X|$. For $|X| = 0$ there is nothing to prove. For $|X| = |Y| + 1$, let $M_{l+1}$ be such that $\langle M_0, M_1, \ldots, M_l, M_{l+1}\rangle$ strongly fulfills $S$. Applying the claim for $Y$, we see that $M$ contains a fulfillment tree $\langle M'_\tau : \tau \in T\rangle$ for $S$ beginning with $\langle M_0, M_1, \ldots, M_l, M_{l+1}\rangle$ such that

$$|\mathrm{KB}(T)| = |Y| + l + 1 = |X| + l.$$

Suppose now that $|X|$ is a limit ordinal, say $X = \sum_{n\in\mathbb{N}} X_n$ where $0 < |X_n| < |X|$ (see definition V.6.7). We may assume that each $|X_n|$ is a successor ordinal, say $|X_n| = |Y_n| + 1$. Let $M_{l+1}$ be such that $\langle M_0, M_1, \ldots, M_l, M_{l+1}\rangle$ strongly fulfills $S$. Applying the claim for each $Y_n$, we see that for each $n$, $M$ contains a fulfillment tree $\langle M'_\tau : \tau \in T_n\rangle$ for $S$ beginning with $\langle M_0, M_1, \ldots, M_l, M_{l+1}\rangle$ such that $|\mathrm{KB}(T_n)| = |Y_n| + l + 1 = |X_n| + l$. By $\Sigma^1_1$ choice within $M$, we see that $M$ contains a sequence of fulfillment trees

$$\langle \langle M'_\tau : \tau \in T_n\rangle : n \in \mathbb{N}\rangle$$

as above. We can arrange these trees so that, for each $n$,

$$\langle 0, 1, \ldots, l-1, n\rangle$$

is the unique element of $T_n$ of length $l+1$. Now put $T = \bigcup_{n\in\mathbb{N}} T_n$. Then $\langle M'_\tau : \tau \in T\rangle$ belongs to $M$ and is a fulfillment tree for $S$ beginning with $\langle M_0, M_1, \ldots, M_l\rangle$, and $|\mathrm{KB}(T)| = |X| + l$. This completes the proof of our claim.

Lemma VIII.6.22 follows immediately from the above claim. □

PROOF OF THEOREM VIII.6.12. Let $S \supseteq \mathsf{ATR}_0$ be a recursive set of $\mathrm{L}_2$-sentences, and let $M$ be a countable $\omega$-model of $S$. If $M$ is a $\beta$-model, then clearly

$$M \models \exists \text{ countable coded } \omega\text{-model of } S,$$

so the theorem holds in this case. Assume now that $M$ is not a $\beta$-model. Since $M \models \mathsf{ATR}_0$, we have by lemma VIII.4.1 that $M \models \Sigma^1_1$ choice. Then

lemma VIII.6.22 tells us that for all countable well orderings $X$, $X \in M$ implies

$$M \models \exists \text{ fulfillment tree } \langle M_\tau : \tau \in T \rangle \text{ for } S \text{ such that } |\mathrm{KB}(T)| = |X|. \tag{24}$$

Hence, by lemma VIII.6.16, there exists $X \in M$ such that $X$ is not a well ordering, yet (24) holds and $M \models \mathrm{WO}(X)$. Let $\langle M_\tau : \tau \in T \rangle$ be as in (24). Standing outside $M$, we see that $\mathrm{KB}(T)$ is not well ordered, hence by lemma V.1.3 there exists a path $f$ through $T$. Put

$$M' = \bigcup_{n \in \mathbb{N}} M_{f[n]}.$$

Thus $M' \subseteq_\omega \bigcup_{\tau \in T} M_\tau \subseteq_\omega M$. Moreover $M' \neq M$ since $\langle M_\tau : \tau \in T \rangle$ is coded as an element of $M$. Finally, we have $M' \models S$ by lemma VIII.6.20 since $\langle M_\tau : \tau \in T \rangle$ is a fulfillment tree for $S$. This completes the proof of theorem VIII.6.12. □

EXERCISE VIII.6.23 (intersection of $\omega$-submodels). Prove the following refinement of theorem VIII.6.12. Let $S$ be an $X$-recursive set of $\mathrm{L}_2$-sentences mentioning $X$ as a parameter. Assume that $S$ includes the axioms of $\mathsf{ATR}_0$. Let $M$ be a countable $\omega$-model such that $X \in M$ and $M$ satisfies $S$. Then $\mathrm{HYP}(X)^M$ is the intersection of all $\omega$-submodels $M' \subseteq_\omega M$ such that $X \in M'$ and $M'$ satisfies $S$. Moreover, for any $Y \in M$ such that $M \models \forall i\, ((Y)_i \not\leq_{\mathrm{H}} X)$, there exists $M' \subseteq_\omega M$ such that $X \in M'$ and $\forall i\, ((Y)_i \notin M')$ and $M'$ satisfies $S$.

**Notes for §VIII.6.** Corollary VIII.6.6 is essentially due to Gandy/Kreisel/Tait [89]; it can also be derived from a result in model theory known as the omitting types theorem; see e.g., Chang/Keisler [35] and Sacks [210]. The use of the term "hard core" to describe results such as corollary VIII.6.6 is apparently due to Kreisel. Theorems VIII.6.5 and VIII.6.7 are due to Simpson [234], as are theorem VIII.6.8 and its corollaries. Theorem VIII.6.12 and corollary VIII.6.13 are due to Quinsey [204, pages 93–96]. Corollary VIII.6.14 was proved earlier by Friedman [67].

In connection with lemma VIII.6.15, Simpson [235] has shown that $\mathsf{ATR}_0$ plus $\Sigma^1_1$-$\mathsf{IND}$ is equivalent to $\Sigma^1_1$-$\mathsf{TI}_0$. This corrects and improves an earlier result of Friedman [69, theorem 8] and Steel [256, page 22].

## VIII.7. Conclusions

The main focus of this chapter has been the existence and non-existence of minimum $\omega$-models of particular subsystems of $\mathsf{Z}_2$. We have seen that the minimum $\omega$-models of $\mathsf{RCA}_0$, $\mathsf{ACA}_0$, and $\Sigma^1_1$-$\mathsf{AC}_0$ are REC, ARITH, and HYP respectively (§§VIII.1, VIII.4). On the other hand, for recursive

$T_0 = \mathsf{WKL}_0$ or $T_0 \supseteq \mathsf{ATR}_0$, $T_0$ does not have a minimum $\omega$-model. Indeed, every model of $T_0$ has a proper $\omega$-submodel which is again a model of $T_0$ (VIII.2.7, VIII.6.12). Moreover, REC is the intersection of all $\omega$-models of $\mathsf{WKL}_0$ but does not itself satisfy $\mathsf{WKL}_0$ (§VIII.2), and HYP is the intersection of all $\beta$-models of $\mathsf{ATR}_0$ but does not itself satisfy $\mathsf{ATR}_0$ (§VIII.6).

In §VIII.4 we used formalized hyperarithmetical theory and pseudo-hierarchies to obtain the following inner model result: $\mathsf{ATR}_0$ proves the existence of sufficiently many countable coded $\omega$-models of $\Sigma^1_1$-$\mathsf{AC}_0$. This has been applied to prove mathematical theorems in $\mathsf{ATR}_0$; see remark V.10.1. In §VIII.5 we used $\omega$-model incompleteness and reflection to obtain another interesting result: $\mathsf{ATR}_0$ does not prove $\Sigma^1_1$ dependent choice.

Chapter IX

# NON-$\omega$-MODELS

The purpose of this chapter is to study certain logical properties of various $L_2$-theories. The main results of the chapter are *conservation results*, i.e., theorems to the effect that an apparently stronger theory $T_0'$ is *conservative* over an apparently weaker theory $T_0$ with respect to a certain class of sentences. (See definition VII.5.12.) Of particular interest is the case when the minimum $\omega$-models of $T_0$ and $T_0'$ are not the same. In such a situation, non-$\omega$-models play an essential role.

A *non-$\omega$-model* is any model $M$ for the language of second order arithmetic whose first order part $(|M|, +_M, \cdot_M, 0_M, 1_M, <_M)$ is not isomorphic to the intended model of first order arithmetic, $(\omega, +, \cdot, 0, 1, <)$. This means that there exists $v \in |M|$ such that for all $n \in \omega$, $M \models n < v$. One important difference between $\omega$-models and non-$\omega$-models is that non-$\omega$-models do not automatically satisfy full induction. For all of the results of the present chapter, it is crucial that our subsystems of $Z_2$ contain only restricted induction.

Many of the results in chapters VII and VIII, on $\beta$-models and $\omega$-models, were formulated in a general way so as to apply to non-$\omega$-models as well. However, the model-theoretic constructions in those chapters always had the feature that the first order part of the constructed model was the same as that of a previously given model. Because of this limitation, many of the deeper conservation theorems cannot be proved by the methods of chapters VII and VIII. Only here, in chapter IX, do we focus on more radical methods of model construction, in which the integers of the new model are different from those of the given one.

In §IX.1 we show that $\mathsf{ACA}_0$ is conservative over PA (first order Peano arithmetic) while $\mathsf{RCA}_0$ is conservative over $\Sigma^0_1$-PA (the fragment of PA with induction restricted to $\Sigma^0_1$ formulas). These results are proved by a straightforward expansion of the given first order model. The integers are not changed, and the only nontrivial point is to show that the expansion preserves sufficient induction.

In §IX.2 we show that $\mathsf{WKL}_0$ has the same first order part as $\mathsf{RCA}_0$. In fact, $\mathsf{WKL}_0$ is conservative over $\mathsf{RCA}_0$ for $\Pi^1_1$ sentences. This result is proved by forcing over a given countable model of $\mathsf{RCA}_0$. The forcing conditions are infinite trees of sequences of 0's and 1's. Again, the first

order part of the given model is unchanged, and the key point is to verify that $\Sigma^0_1$ induction is preserved.

In §IX.3 we introduce the formal system PRA of primitive recursive arithmetic. We prove that $\mathsf{WKL}_0$ is conservative over PRA for $\Pi^0_2$ sentences. The proof of this deep result involves a genuine application of non-$\omega$-models. Namely, the integers of the constructed model of $\mathsf{WKL}_0$ are obtained as a certain proper initial segment of the integers of the given model of PRA. At the end of the section we point out that this result is of great philosophical significance in connection with Hilbert's foundational program of finitistic reductionism.

In §IX.4 we use saturated models to prove various conservation results involving the comprehension and choice schemes which were studied in §§VII.5–VII.7. We show that, for all $k < \omega$, $\Delta^1_{k+1}$ comprehension is conservative over $\Pi^1_k$ comprehension for $\Pi^1_l$ sentences, $l = \min\{k+2, 4\}$. This may seem rather surprising in view of the results of §VII.7, according to which the minimum $\beta$-model of $\Delta^1_{k+1}$ comprehension is much bigger than that of $\Pi^1_k$ comprehension. It is essential here that the systems we are dealing with have only restricted induction, thus allowing greater freedom to construct non-$\omega$-models.

Although the main focus of this chapter is on model-theoretic methods, many of the theorems can be given alternative proofs using syntactical, i.e., proof-theoretic, methods. Such methods involve a direct analysis of the structure of proofs. For example, the proof-theoretic approach to showing that $T_0'$ is conservative over $T_0$ for $\Pi^1_k$ sentences would be to exhibit an explicit, primitive recursive method whereby any given $T_0'$-proof of a $\Pi^1_k$ sentence can be transformed into a $T_0$-proof of the same sentence. In addition, proof theory can be used to obtain many other results about subsystems of $\mathsf{Z}_2$ which are apparently inaccessible to model-theoretic methods. In §IX.5 we briefly discuss Gentzen-style proof theory, emphasizing provable ordinals and combinatorial independence results.

## IX.1. The First Order Parts of $\mathsf{RCA}_0$ and $\mathsf{ACA}_0$

Recall that $\mathrm{L}_1$ and $\mathrm{L}_2$ are the languages of first and second order arithmetic, respectively. If $T_0$ is any $\mathrm{L}_2$-theory, the first order part of $T_0$ is the $\mathrm{L}_1$-theory whose theorems are exactly the $\mathrm{L}_1$-formulas which are theorems of $T_0$. In this section and the next, we shall determine the first order parts of $\mathsf{RCA}_0$, $\mathsf{ACA}_0$ and $\mathsf{WKL}_0$. Our methods involve non-$\omega$-models of the theories in question.

LEMMA IX.1.1. $\mathsf{ACA}_0$ *proves all instances of arithmetical induction*:

$$(\varphi(0) \wedge \forall n\,(\varphi(n) \to \varphi(n+1))) \to \forall n\,\varphi(n) \tag{25}$$

*where $\varphi(n)$ is any arithmetical formula.*

Proof. We reason in $\mathsf{ACA}_0$. By arithmetical comprehension, form the set $X$ consisting of all $n$ such that $\varphi(n)$ holds. Then (25) follows from the induction axiom

$$(0 \in X \wedge \forall n\,(n \in X \to n+1 \in X)) \to \forall n\,(n \in X).$$

This completes the proof. □

Definition IX.1.2. If

$$M = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$

is any $\mathrm{L}_2$-structure, *the first order part of* $M$ is the $\mathrm{L}_1$-structure

$$(|M|, +_M, \cdot_M, 0_M, 1_M, <_M).$$

Lemma IX.1.3. *Let $M$ be any $\mathrm{L}_2$-structure which satisfies the basic axioms* I.2.4(i) *plus arithmetical induction. Then $M$ is an $\omega$-submodel of some model of $\mathsf{ACA}_0$. In other words, we can find a model $M'$ of $\mathsf{ACA}_0$ such that* (1) *$M$ is a submodel of $M'$*, (2) *$M$ and $M'$ have the same first order part.*

Proof. Let $M$ be as in the hypothesis of the lemma. A set $X \subseteq |M|$ is said to be *arithmetically definable over $M$* if there exists an arithmetical formula $\varphi(n)$ with parameters from $|M| \cup \mathcal{S}_M$ and no free variables other than $n$, such that

$$X = \{a \in |M| \colon M \models \varphi(a)\}. \tag{26}$$

Let $M'$ be the $\mathrm{L}_2$-structure with the same first order part as $M$ and

$$\begin{aligned}\mathcal{S}_{M'} &= \text{Arith-Def}(M)\\ &= \{X \subseteq |M| \colon X \text{ is arithmetically definable over } M\}.\end{aligned}$$

Obviously $M \subseteq_\omega M'$. We claim that $M'$ is a model of $\mathsf{ACA}_0$. Trivially the basic axioms I.2.4(i) are satisfied in $M'$. Let $X \in \mathcal{S}_{M'}$ be given as in (26). Since

$$M \models (\varphi(0) \wedge \forall n\,(\varphi(n) \to \varphi(n+1))) \to \forall n\,\varphi(n),$$

it follows that

$$M' \models (0 \in X \wedge \forall n\,(n \in X \to n+1 \in X)) \to \forall n\,(n \in X).$$

This shows that $M'$ satisfies the induction axiom I.2.4(ii).

It remains to prove that $M'$ satisfies arithmetical comprehension (definition III.1.2). Let $\varphi(n)$ be an arithmetical formula with parameters from $|M| \cup \mathcal{S}_{M'}$ and no free variables other than $n$. Exhibiting the parameters, we have

$$\varphi(n) \equiv \varphi(n, b_1, \ldots, b_k, Y_1, \ldots, Y_l)$$

where $b_1, \ldots, b_k \in |M|$ and $Y_1, \ldots, Y_l \in \mathcal{S}_{M'}$. For $j = 1, \ldots, l$, we have

$$Y_j = \{b \in |M| \colon M \models \varphi_j(b)\}$$

where $\varphi_j(m)$ is arithmetical with parameters from $|M| \cup \mathcal{S}_M$ and no free variables other than $m$. Let $\widetilde{\varphi}(n)$ be the result of replacing all atomic formulas $t \in Y_j$ in $\varphi(n)$ by $\varphi_j(t)$, for $j = 1, \ldots, l$. Then $\widetilde{\varphi}(n)$ is arithmetical with parameters from $|M| \cup \mathcal{S}_M$ and no free variables other than $n$. Hence by definition of $M'$ we have

$$M' \models \exists X \, \forall n \, (n \in X \leftrightarrow \widetilde{\varphi}(n)),$$

namely $X = \{a \in |M| \colon M \models \widetilde{\varphi}(a)\} \in \text{Arith-Def}(M)$. Moreover

$$M' \models \forall n \, (\varphi(n) \leftrightarrow \widetilde{\varphi}(n)).$$

Combining the last two formulas, we get

$$M' \models \exists X \, \forall n \, (n \in X \leftrightarrow \varphi(n)).$$

Thus $M'$ satisfies arithmetical comprehension. The proof of lemma IX.1.3 is complete. □

DEFINITION IX.1.4 (Peano arithmetic). *First order Peano arithmetic*, denoted $\mathsf{Z}_1$ or PA, is the $\mathrm{L}_1$-theory whose axioms are the basic axioms I.2.4(i) plus *full first order induction*, i.e.,

$$(\varphi(0) \wedge \forall n \, (\varphi(n) \to \varphi(n+1))) \to \forall n \, \varphi(n)$$

for all $\mathrm{L}_1$-formulas $\varphi(n)$.

THEOREM IX.1.5. *An* $\mathrm{L}_1$*-structure*

$$(|M|, +_M, \cdot_M, 0_M, 1_M, <_M) \tag{27}$$

*is the first order part of some model of* $\mathsf{ACA}_0$ *if and only if it is a model of* PA.

PROOF. If (27) is the first order part of some model of $\mathsf{ACA}_0$, then by lemma IX.1.1 it satisfies PA. Conversely, if (27) is a model of PA, then viewed as an $\mathrm{L}_2$-structure it is a model of arithmetical induction, so by lemma IX.1.3 we can find a model $M'$ of $\mathsf{ACA}_0$ whose first order part is (27). This completes the proof. □

COROLLARY IX.1.6 (first order part of $\mathsf{ACA}_0$). PA *is the first order part of* $\mathsf{ACA}_0$.

PROOF. Lemma IX.1.1 implies that PA is included in the first order part of $\mathsf{ACA}_0$. For the converse, let $\varphi$ be an $\mathrm{L}_1$-sentence which is not a theorem of PA. By Gödel's completeness theorem, there exists a model (27) of PA in which $\varphi$ fails. By theorem IX.1.5, this (27) is then the first order part of some model of $\mathsf{ACA}_0$. Thus we have a model of $\mathsf{ACA}_0$ in which $\varphi$ fails. Hence, by the soundness theorem, $\varphi$ is not a theorem of $\mathsf{ACA}_0$. This completes the proof. □

REMARK IX.1.7. In the style of definition VII.5.12, we may restate corollary IX.1.6 by saying that $\mathsf{ACA}_0$ *is a conservative extension of* PA. Similarly, corollary IX.1.11 below says that $\mathsf{RCA}_0$ is a conservative extension of $\Sigma^0_1$-PA.

Lemma IX.1.8. *Let $M$ be any $\mathrm{L}_2$-structure which satisfies the basic axioms* I.2.4(i) *plus the $\Sigma^0_1$ induction scheme* II.1.3. *Then $M$ is an $\omega$-submodel of some model of* $\mathsf{RCA}_0$.

Proof. Note first that the basic axioms plus $\Sigma^0_1$ induction imply $\Sigma^0_1$ *bounding principle*:

$$(\forall i < m)\, \exists j\, \varphi(i, j) \to \exists n\, (\forall i < m)\, (\exists j < n)\, \varphi(i, j)$$

where $\varphi(i, j)$ is any $\Sigma^0_1$ formula in which $n$ does not occur freely. This is easily proved by $\Sigma^0_1$ induction on $m$.

Let $M$ be as in the hypothesis of our lemma. We say that $X \subseteq |M|$ is $\Delta^0_1$ *definable over $M$* if there exist a $\Sigma^0_1$ formula $\varphi(n)$ and a $\Pi^0_1$ formula $\psi(n)$, with parameters from $|M| \cup \mathcal{S}_M$ and no free variables other than $n$, such that

$$\begin{aligned} X &= \{a \in |M| \colon M \models \varphi(a)\} \\ &= \{a \in |M| \colon M \models \psi(a)\}. \end{aligned}$$

We define $M'$ to be the $\mathrm{L}_2$-structure with the same first order part as $M$ and

$$\begin{aligned} \mathcal{S}_{M'} &= \Delta^0_1\text{-Def}(M) \\ &= \{X \subseteq |M| \colon X \text{ is } \Delta^0_1 \text{ definable over } M\}. \end{aligned}$$

Clearly $M$ is an $\omega$-submodel of $M'$.

In order to prove that $M'$ is a model of $\mathsf{RCA}_0$, we first prove two claims.

Our first claim is that, for any $\Sigma^0_0$ formula $\theta$ with parameters from $|M| \cup \mathcal{S}_{M'}$ and no free set variables, we can find a $\Sigma^0_1$ formula $\theta_\Sigma$ and a $\Pi^0_1$ formula $\theta_\Pi$ with parameters from $|M| \cup \mathcal{S}_M$ and with the same free variables as $\theta$, such that $\theta_\Sigma$ and $\theta_\Pi$ are equivalent to $\theta$ over $M'$. In proving this claim, we may assume without loss that $\theta$ is built from atomic formulas by means of negation, conjunction, and bounded universal quantification. The claim is proved by induction on $\theta$. If $\theta$ is atomic of the form $t_1 = t_2$ or $t_1 < t_2$, we define $\theta_\Sigma \equiv \theta_\Pi \equiv \theta$. If $\theta$ is atomic of the form $t \in X$, then $X$ is a parameter from $\mathcal{S}_{M'}$ and we define $\theta_\Sigma = \varphi(t)$ and $\theta_\Pi \equiv \psi(t)$, where $\varphi(n)$ and $\psi(n)$ are as in the $\Delta^0_1$ definition of $X$ over $M$. If $\theta \equiv \neg\theta'$, put $\theta_\Sigma \equiv \neg\theta'_\Pi$ and $\theta_\Pi \equiv \neg\theta'_\Sigma$. If $\theta \equiv \theta' \wedge \theta''$, put

$$\theta_\Sigma \equiv \theta'_\Sigma \wedge \theta''_\Sigma \equiv \exists m\, ((\exists j' < m)\, \theta'_0(j') \wedge (\exists j'' < m)\, \theta''_0(j''))$$

where $\theta'_\Sigma \equiv \exists j\, \theta'_0(j)$ and $\theta''_\Sigma \equiv \exists j\, \theta''_0(j)$. Also, put

$$\theta_\Pi \equiv \theta'_\Pi \wedge \theta''_\Pi \equiv \forall j\, (\theta'_1 \wedge \theta''_1)$$

where $\theta'_\Pi \equiv \forall j\, \theta'_1$ and $\theta''_\Pi \equiv \forall j\, \theta''_1$. Finally, if $\theta \equiv (\forall i < t)\, \theta'$, put

$$\theta_\Sigma \equiv \exists n\, (\forall i < t)\, (\exists j < n)\, \theta'_0$$

and

$$\theta_\Pi \equiv \forall j\, (\forall i < t)\, \theta'_1$$

where $\theta'_\Sigma \equiv \exists j\, \theta'_0$ and $\theta'_\Pi \equiv \forall j\, \theta'_1$. The equivalence of $\theta_\Sigma$ with $\theta$ over $M$ follows from the $\Sigma^0_1$ bounding principle. This completes the proof of the first claim.

Our second claim is that, for any $\Sigma^0_1$ formula $\varphi$ with parameters from $|M| \cup \mathcal{S}_{M'}$ and no free set variables, we can find an equivalent $\Sigma^0_1$ formula $\varphi'$ with the same free variables and with parameters from $|M| \cup \mathcal{S}_M$ only. To see this, write $\varphi \equiv \exists j\, \theta$ where $\theta$ is $\Sigma^0_0$, and put

$$\varphi' \equiv \exists j\, \theta_\Sigma \equiv \exists j\, \exists m\, \theta_0 \equiv \exists k\, (\exists j < k)\, (\exists m < k)\, \theta_0$$

where $\theta_\Sigma \equiv \exists m\, \theta_0$ is as in our first claim, above.

We are now ready to prove that $M'$ is a model of $\mathsf{RCA}_0$. Trivially $M'$ satisfies the basic axioms I.2.4(i). Given a $\Sigma^0_1$ formula $\varphi(n)$, letting $\varphi'(n)$ be as in our second claim, we have

$$M \models (\varphi'(0) \wedge \forall n\, (\varphi'(n) \to \varphi'(n+1))) \to \forall n\, \varphi'(n),$$

hence

$$M' \models (\varphi(0) \wedge \forall n\, (\varphi(n) \to \varphi(n+1))) \to \forall n\, \varphi(n)$$

so $M'$ satisfies $\Sigma^0_1$ induction. Now assume that

$$M' \models \forall n\, (\varphi(n) \leftrightarrow \psi(n))$$

where $\varphi(n)$ and $\psi(n)$ are respectively $\Sigma^0_1$ and $\Pi^0_1$ with parameters from $|M| \cup \mathcal{S}_{M'}$. By our second claim, we can find equivalent $\Sigma^0_1$ and $\Pi^0_1$ formulas $\varphi'(n)$ and $\psi'(n)$ with parameters from $|M| \cup \mathcal{S}_M$ only. Thus

$$M' \models \forall n\, (\varphi(n) \leftrightarrow \varphi'(n))$$

and

$$M \models \forall n\, (\varphi'(n) \leftrightarrow \psi'(n)).$$

Putting $X = \{a \in |M| \colon M \models \varphi'(a)\} = \{a \in |M| \colon M \models \psi'(a)\}$, we see that $X \in \Delta^0_1\text{-Def}(M) = \mathcal{S}_{M'}$, hence

$$M' \models \exists X\, \forall n\, (n \in X \leftrightarrow \varphi(n)).$$

Thus $M'$ satisfies $\Delta^0_1$ comprehension.

This completes the proof of lemma IX.1.8. □

DEFINITION IX.1.9. For $0 \le k < \omega$, $\Sigma^0_k$-PA is the $L_1$-theory consisting of the basic axioms I.2.4(i) plus the induction scheme (25) for all $\Sigma^0_k$ $L_1$-formulas.

THEOREM IX.1.10. *An* $L_1$*-structure* (27) *is the first order part of some model of* $\mathsf{RCA}_0$ *if and only if it is a model of* $\Sigma^0_1$-PA.

PROOF. Obviously the first order part of any model of $\mathsf{RCA}_0$ satisfies $\Sigma^0_1$-PA. Conversely, if (27) is a model of $\Sigma^0_1$-PA, then viewed as an $L_2$-structure it is a model of $\Sigma^0_1$ induction, hence by lemma IX.1.8 it is the first order part of some model of $\mathsf{RCA}_0$. □

Corollary IX.1.11 (first order part of $\mathsf{RCA}_0$). *The first order part of* $\mathsf{RCA}_0$ *is* $\Sigma^0_1$-PA.

Proof. Since the axioms of $\mathsf{RCA}_0$ include those of $\Sigma^0_1$-PA, it is obvious that the first order part of $\mathsf{RCA}_0$ includes $\Sigma^0_1$-PA. For the converse, proceed as in the proof of corollary IX.1.6 using theorem IX.1.10 instead of theorem IX.1.5. □

**Notes for §IX.1.** The results of this section are essentially due to Friedman [69]. For more information on models of $\Sigma^0_k$-PA, $0 \leq k < \omega$, see Hájek/Pudlák [100] and Kaye [137].

## IX.2. The First Order Part of $\mathsf{WKL}_0$

In this section we shall show that the first order part of $\mathsf{WKL}_0$ is the same as that of $\mathsf{RCA}_0$. This is a previously unpublished result of Harrington. Our proof will employ a kind of forcing argument in which the forcing conditions are trees.

Theorem IX.2.1. *Let $M$ be any countable model of* $\mathsf{RCA}_0$. *Then $M$ is an $\omega$-submodel of some countable model of* $\mathsf{WKL}_0$.

The proof will be based on the following notion of genericity.

Definition IX.2.2. Let $M$ be a model of $\mathsf{RCA}_0$.

1. We define $\mathcal{T}_M$ to be the set of all $T \in \mathcal{S}_M$ such that
$$M \models T \text{ is an infinite subtree of } 2^{<\mathbb{N}}.$$
For $T \in \mathcal{T}_M$ and $X \subseteq |M|$, we say that $X$ *is a path through* $T$ if, for all $b \in |M|$, $X[b] \in T$. Here $X[b] \in T$ means that there exists $\sigma \in |M|$ such that $M \models \sigma \in T$ and $\mathrm{lh}(\sigma) = b$, and for all $a <_M b$, $a \in X$ if and only if $M \models \sigma(a) = 1$.
2. We say that $\mathcal{D} \subseteq \mathcal{T}_M$ is *dense* if for all $T \in \mathcal{T}_M$ there exists $T' \in \mathcal{D}$ such that $T' \subseteq T$. We say that $\mathcal{D}$ is $M$*-definable* if there exists a formula $\varphi(X)$ with parameters from $|M| \cup \mathcal{S}_M$ and no free variables other than $X$, such that for all $T \in \mathcal{T}_M$, $M \models \varphi(T)$ if and only if $T \in \mathcal{D}$.
3. We say that $G \subseteq |M|$ is $\mathcal{T}_M$*-generic* if for every dense, $M$-definable $\mathcal{D} \subseteq \mathcal{T}_M$ there exists $T \in \mathcal{D}$ such that $G$ is a path through $T$.

Lemma IX.2.3. *Let $M$ be a countable model of* $\mathsf{RCA}_0$. *Given $T \in \mathcal{T}_M$, we can find a $\mathcal{T}_M$-generic $G \subseteq |M|$ such that $G$ is a path through $T$.*

Proof. Since $M$ is countable, the set of all dense $M$-definable sets $\mathcal{D} \subseteq \mathcal{T}_M$ is countable. Let $\langle \mathcal{D}_i : i < \omega \rangle$ be an enumeration of these dense sets. Given $T \in \mathcal{T}_M$, we can find a sequence of trees $T_i$, $i < \omega$, such that $T_0 = T$, $T_{i+1} \subseteq T_i$, and $T_{i+1} \in \mathcal{D}_i$ for all $i < \omega$. We are going to show that there is a unique $G$ such that, for all $i < \omega$, $G$ is a path through $T_i$. To see this, define

$\mathcal{E}_b$ for each $b \in |M|$ to be the set of $T \in \mathcal{T}_M$ such that $T$ contains exactly one sequence of length $b$. Clearly $\mathcal{E}_b$ is dense and $M$-definable. Let $i_b$ be such that $\mathcal{E}_b = \mathcal{D}_{i_b}$, and let $\tau_b$ be the unique sequence of length $b$ such that $\tau_b \in T_{i_b+1}$. Clearly $b <_M c$ implies $\tau_b \subseteq \tau_c$. Let $G$ be the unique subset of $|M|$ whose characteristic function is $\bigcup_{b\in|M|} \tau_b$. Clearly $\tau_b \in T_i$ for all $b \in |M|$ and all $i < \omega$. Hence, for all $i < \omega$, $G$ is a path through $T_i$. It follows by construction that $G$ is $\mathcal{T}_M$-generic. This proves lemma IX.2.3. □

LEMMA IX.2.4. *Let $M$ be a model of* $\mathsf{RCA}_0$ *and suppose that $G \subseteq |M|$ is $\mathcal{T}_M$-generic. Let $M'$ be the* $\mathrm{L}_2$*-structure with the same first order part as $M$ and $\mathcal{S}_{M'} = \mathcal{S}_M \cup \{G\}$. Then $M'$ satisfies $\Sigma^0_1$ induction.*

PROOF. It suffices to prove the following. For any $b \in |M|$ and any $\Sigma^0_1$ formula $\varphi(i, X)$ with parameters from $|M| \cup \mathcal{S}_M$ and no free variables other than $i$ and $X$, the set $\{a\colon a <_M b \wedge M' \models \varphi(a, G)\}$ is $M$-finite. (From this it is clear that $M'$ satisfies $\Sigma^0_1$ induction.)

In order to prove this, assume first that $\varphi(i, X)$ is in *normal form*, i.e., $\varphi(i, X) \equiv \exists j\, \theta(i, X[j])$ where $\theta(i, \tau)$ is $\Sigma^0_0$ with parameters from $|M| \cup \mathcal{S}_M$. (Later we shall show how to eliminate this assumption.) Let $\mathcal{D}_b$ be the set of $T \in \mathcal{T}_M$ such that, for each $a <_M b$, $M$ satisfies either

(i) $\forall\tau\, (\tau \in T \to \neg\theta(a, \tau))$

or

(ii) $\exists k\, \forall\tau\, ((\tau \in T \wedge \mathrm{lh}(\tau) = k) \to (\exists j \leq k)\, \theta(a, \tau[j]))$

where $\tau[j]$ denotes the initial sequence of $\tau$ of length $j$. The motivation here is that if $G$ is a path through $T$, then (i) gives $\neg\varphi(a, G)$ while (ii) gives $\varphi(a, G)$.

We claim that $\mathcal{D}_b$ is dense in $\mathcal{T}_M$. To see this, let $T \in \mathcal{T}_M$ be given. Working within $M$, for each $\sigma \in (2^{<\mathbb{N}})^M$ define a tree $T_\sigma$ as follows: $T_{\langle\rangle} = T$; $T_{\sigma^\frown\langle 0\rangle} = \{\tau \in T_\sigma\colon (\forall j \leq \mathrm{lh}(\tau))\, \neg\theta(a, \tau[j])\}$ where $a = \mathrm{lh}(\sigma)$; and $T_{\sigma^\frown\langle 1\rangle} = T_\sigma$. Set $S_b = \{\sigma\colon \mathrm{lh}(\sigma) = b \wedge T_\sigma \text{ is infinite}\}$. Since $M$ satisfies bounded $\Sigma^0_1$ comprehension (theorem II.3.9), $S_b$ is $M$-finite. Moreover $S_b$ is nonempty since, for instance, $\langle 1, 1, \ldots, 1\rangle$ (with $b$ 1's) is an element of $S_b$. Now let $\sigma_b$ be the lexicographically least element of $S_b$. We are going to show that $T_{\sigma_b}$ belongs to $\mathcal{D}_b$. To see this, let $a <_M b$ be given. If $\sigma_b(a) = 0$, then

$$\begin{aligned} T_{\sigma_b} &\subseteq T_{\sigma_b[a]^\frown\langle 0\rangle} \\ &= \{\tau \in T_{\sigma_b[a]}\colon (\forall j \leq \mathrm{lh}(\tau))\, \neg\theta(a, \tau[j])\} \\ &\subseteq \{\tau\colon \neg\theta(a, \tau)\} \end{aligned}$$

so in this case (i) holds. If $\sigma_b(a) = 1$, then $T_{\sigma_b[a]^\frown\langle 0\rangle}$ is $M$-finite, i.e., $M$ satisfies

$$\exists k\, \forall\tau\, ((\tau \in T_{\sigma_b[a]} \wedge \mathrm{lh}(\tau) = k) \to (\exists j \leq k)\, \theta(a, \tau[j])),$$

so in this case (ii) holds. This completes the proof that $\mathcal{D}_b$ is dense.

In addition, $\mathcal{D}_b$ is $M$-definable, so let $T' \in \mathcal{D}_b$ be such that $G$ is a path through $T'$. By bounded $\Sigma^0_1$ comprehension within $M$, there exists an $M$-finite set $Y$ consisting of all $a <_M b$ such that $M$ satisfies (ii) for $T'$ and $a$. We then have:

$$\begin{aligned} Y &= \{a\colon a <_M b \wedge M' \models \exists j\, \theta(a, G[j])\} \\ &= \{a\colon a <_M b \wedge M' \models \varphi(a, G)\}. \end{aligned}$$

This completes the proof under the assumption that $\varphi(i, X)$ is in normal form.

It remains to eliminate this assumption. For this, it suffices to prove the following claim: for every $\Sigma^0_1$ formula $\varphi(X)$ with parameters from $|M| \cup \mathcal{S}_M$ and no free set variables other than $X$, we can find another such formula $\overline{\varphi}(X)$ which is in normal form and such that $M'$ satisfies $\varphi(G) \leftrightarrow \overline{\varphi}(G)$. We shall first prove our claim when $\varphi(X)$ is $\Sigma^0_0$, by induction on $\varphi(X)$. The most interesting case is when $\varphi(X)$ is of the form $(\forall i < t)\, \varphi'(i, X)$. By inductive hypothesis, we may assume that $\varphi'(i, X)$ is in normal form, say $\varphi'(i, X) \equiv \exists j\, \theta(i, X[j])$ where $\theta(i, \tau)$ is $\Sigma^0_0$. Put $\theta'(i, \tau) \equiv (\exists j < \mathrm{lh}(\tau))\, \theta(i, \tau[j])$. If $(\forall i < t)\, \exists j\, \theta(i, G[j])$ holds, then by $\Sigma^0_1$ induction on $m \leq t$ we can prove $\exists n\, (\forall i < m)\, \theta'(i, G[n])$. Thus

$$\begin{aligned} \varphi(G) &\leftrightarrow (\forall i < t)\, \exists j\, \theta(i, G[j]) \\ &\leftrightarrow \exists n\, (\forall i < t)\, \theta'(i, G[n]). \end{aligned}$$

Hence in this case we may take $\overline{\varphi}(X) \equiv \exists n\, (\forall i < t)\, \theta'(i, X[n])$. This proves our claim provided $\varphi(X)$ is $\Sigma^0_0$. Now when $\varphi(X)$ is $\Sigma^0_1$, we have $\varphi(G) \equiv \exists k\, \theta(k, G) \equiv \exists k\, \exists j\, \theta'(k, G[j]) \equiv \exists n\, \theta''(G[n])$ where $\theta'$ and $\theta''$ are appropriate $\Sigma^0_0$ formulas. Thus we may take $\overline{\varphi}(X) \equiv \exists n\, \theta''(X[n])$. This gives our claim.

The proof of lemma IX.2.4 is now complete. □

Lemma IX.2.5. *Let $M$ be a countable model of $\mathsf{RCA}_0$. Given $T \in \mathcal{T}_M$, there exists a countable model $M''$ of $\mathsf{RCA}_0$ such that $M$ is an $\omega$-submodel of $M''$, and $M'' \models T$ has a path.*

Proof. By lemma IX.2.3, let $G$ be a $\mathcal{T}_M$-generic path through $T$. Let $M'$ be the model with the same first order part as $M$ and $\mathcal{S}_{M'} = \mathcal{S}_M \cup \{G\}$. Then $M$ is an $\omega$-submodel of $M'$, and by lemma IX.2.4, $M'$ satisfies the $\Sigma^0_1$ induction scheme. By lemma IX.1.8, we can find a countable model $M''$ of $\mathsf{RCA}_0$ such that $M'$ is an $\omega$-submodel of $M''$. This completes the proof. □

Proof of theorem IX.2.1. Use lemma IX.2.5 repeatedly to form a sequence of countable $\omega$-models

$$M = M_0 \subseteq_\omega M_1 \subseteq_\omega \cdots \subseteq_\omega M_i \subseteq_\omega \cdots \qquad (i < \omega)$$

where each $M_i$ is a model of $\mathsf{RCA}_0$ and for all $T \in \mathcal{T}_{M_i}$ there exists $j > i$ such that $M_j \models T$ has a path. Let $M^*$ be the union of this sequence of models. Then clearly $M \subseteq_\omega M^*$. Moreover $M^* \models \mathsf{RCA}_0$ and, for all $T \in \mathcal{T}_{M^*}$, $M^* \models T$ has a path. Thus $M^*$ is a countable $\omega$-model of $\mathsf{WKL}_0$. This completes the proof. □

The following corollary may be expressed by saying that $\mathsf{WKL}_0$ *is conservative over* $\mathsf{RCA}_0$ *for* $\Pi^1_1$ *sentences*. (This terminology is explained in definition VII.5.12.)

COROLLARY IX.2.6 (conservation theorem). *For any* $\Pi^1_1$ *sentence* $\psi$, *if* $\psi$ *is a theorem of* $\mathsf{WKL}_0$ *then* $\psi$ *is already a theorem of* $\mathsf{RCA}_0$.

PROOF. Suppose that $\psi$ is a $\Pi^1_1$ sentence which is not a theorem of $\mathsf{RCA}_0$. Then by Gödel's completeness theorem, there exists a countable model $M$ of $\mathsf{RCA}_0$ in which $\psi$ fails. By theorem IX.2.1, let $M^*$ be a model of $\mathsf{WKL}_0$ such that $M$ is an $\omega$-submodel of $M^*$. Writing $\psi$ as $\forall X\, \theta(X)$ where $\theta(X)$ is arithmetical, there exists $X \in \mathcal{S}_M$ such that $M \models \neg\theta(X)$. Since $M^*$ extends $M$ and has the same first order part as $M$, it follows that $M^* \models \neg\theta(X)$. Hence $\psi$ fails in $M^*$. By the soundness theorem, it follows that $\psi$ is not a theorem of $\mathsf{WKL}_0$. This completes the proof. □

COROLLARY IX.2.7 (first order part of $\mathsf{WKL}_0$). *The first order part of* $\mathsf{WKL}_0$ *is the same as that of* $\mathsf{RCA}_0$, *namely* $\Sigma^0_1$-PA.

PROOF. Corollary IX.2.6 implies that $\mathsf{WKL}_0$ and $\mathsf{RCA}_0$ have the same first order part, since every $\mathrm{L}_1$-formula is $\Pi^1_1$. The rest follows from corollary IX.1.11. □

EXERCISE IX.2.8. Let $\mathcal{N}_M$ be the set of $f \in \mathcal{S}_M$ such that $M \models (f$ is a total function from $\mathbb{N}$ into $\mathbb{N})$. For $f, g \in \mathcal{N}_M$, let us say that $f$ *majorizes* $g$ if $f(b) \geq_M g(b)$ for all $b \in |M|$. Prove the following refinement of theorem IX.2.1. Given a countable model $M$ of $\mathsf{RCA}_0$, we can find a countable $\omega$-model $M^*$ of $\mathsf{WKL}_0$ such that $M$ is an $\omega$-submodel of $M^*$ and every $g \in \mathcal{N}_{M^*}$ is majorized by some $f \in \mathcal{N}_M$. (See also theorem VIII.2.21.)

**Notes for §IX.2.** Theorem IX.2.1 is due to Harrington (1977, unpublished, communicated by Friedman). Our proof of theorem IX.2.1 is inspired by the proof of Jockusch/Soare [134, theorem 2.4]. This same Jockusch/Soare construction is also related to the proof of theorem VIII.2.21 and to exercise IX.2.8 above. Simpson (1982, unpublished) has used a different construction to show that theorem IX.2.1 also holds for uncountable models.

## IX.3. A Conservation Result for Hilbert's Program

In this section we shall introduce the formal system PRA of *primitive recursive arithmetic*. We shall then use a model-theoretic method to show that $\mathsf{WKL}_0$ is conservative over PRA for $\Pi^0_2$ sentences. At the end of the section, we shall explain how this conservation result represents a partial realization of Hilbert's program for the foundations of mathematics.

Definition IX.3.1 (language of PRA). The *language of* PRA is a first order language with equality. In addition to the 2-place predicate symbol $=$, it contains a constant symbol $\underline{0}$, number variables $x_0, x_1, \ldots, x_n, \ldots (n < \omega)$, 1-place operation symbols $\underline{Z}$ and $\underline{S}$, $k$-place operation symbols $\underline{P}^k_i$ for each $i$ and $k$ with $1 \leq i \leq k < \omega$, and additional operation symbols, which are introduced as follows. If $\underline{g}$ is an $m$-place operation symbol and $\underline{h}_1, \ldots, \underline{h}_m$ are $k$-place operation symbols, then $\underline{f} = C(\underline{g}, \underline{h}_1, \ldots, \underline{h}_m)$ is an $k$-place operation symbol. If $\underline{g}$ is a $k$-place operation symbol and $\underline{h}$ is a $(k+2)$-place operation symbol, then $\underline{f} = R(\underline{g}, \underline{h})$ is a $(k+1)$-place operation symbol. The operation symbols of the language of PRA are called *primitive recursive function symbols*.

The *intended model of* PRA consists of the nonnegative integers, $\omega = \{0, 1, 2, \ldots\}$, together with the primitive recursive functions. In detail, the number variables range over $\omega$ and we interpret $=$ as equality on $\omega$, $\underline{0}$ as 0, $\underline{Z}$ as the constant zero function $Z$ defined by $Z(x) = 0$, $\underline{S}$ as the successor function $S$ defined by $S(x) = x + 1$, $\underline{P}^k_i$ as the projection function $P^k_i$ defined by

$$P^k_i(x_1, \ldots, x_k) = x_i,$$

$C(\underline{g}, \underline{h}_1, \ldots, \underline{h}_m)$ as the function $f$ defined by composition as

$$f(x_1, \ldots, x_k) = g(h_1(x_1, \ldots, x_k), \ldots, h_m(x_1, \ldots, x_k)),$$

and $R(\underline{g}, \underline{h})$ as the function $f$ defined by primitive recursion as

$$f(0, x_1, \ldots, x_k) = g(x_1, \ldots, x_k)$$
$$f(y+1, x_1, \ldots, x_k) = h(y, f(y, x_1, \ldots, x_k), x_1, \ldots, x_k).$$

Definition IX.3.2 (axioms of PRA). The *axioms of* PRA are as follows. We have the usual axioms for equality. We have the usual axioms for $\underline{0}$ and the successor function:

$$\underline{Z}(x) = \underline{0},$$
$$\underline{S}(x) = \underline{S}(y) \to x = y,$$
$$x \neq \underline{0} \leftrightarrow \exists y\, (\underline{S}(y) = x).$$

We have defining axioms for the projection functions:

$$\underline{P}^k_i(x_1, \ldots, x_k) = x_i.$$

For each function $\underline{f} = C(\underline{g}, \underline{h}_1, \ldots, \underline{h}_m)$ given by composition, we have a defining axiom

$$\underline{f}(x_1, \ldots, x_k) = \underline{g}(\underline{h}_1(x_1, \ldots, x_k), \ldots, \underline{h}_m(x_1, \ldots, x_k)).$$

For each function $\underline{f} = R(\underline{g}, \underline{h})$ given by primitive recursion, we have defining axioms

$$\underline{f}(0, x_1, \ldots, x_k) = \underline{g}(x_1, \ldots, x_k),$$
$$\underline{f}(\underline{S}(y), x_1, \ldots, x_k) = \underline{h}(y, \underline{f}(y, x_1, \ldots, x_k), x_1, \ldots, x_k).$$

Finally we have the scheme of primitive recursive induction:

$$(\theta(0) \wedge \forall x\, (\theta(x) \to \theta(\underline{S}(x)))) \to \forall x\, \theta(x)$$

where $\theta(x)$ is any quantifier-free formula in the language of PRA with a distinguished free number variable $x$. We define PRA, *primitive recursive arithmetic*, to be the formal system with the above axioms.

In general, a *model of* PRA consists of a set $|M|$, a distinguished element $0_M \in |M|$, and a $k$-place function $f_M\colon |M|^k \to |M|$ for each $k$-place primitive recursive function symbol $\underline{f}$, such that the axioms of PRA are true when the number variables range over $|M|$ and we interpret $=$ as equality on $|M|$, $\underline{0}$ as $0_M$, and $\underline{f}$ as $f_M$.

EXERCISE IX.3.3. Prove that PRA can be axiomatized by a set of quantifier-free formulas. (Hint: There are two ways to prove this. The first is to exhibit a set of quantifier-free formulas and prove that they axiomatize PRA. The second way is to prove that every submodel of a model of PRA is again a model of PRA, then apply the theorem of Tarski according to which any first order theory with this property can be axiomatized by quantifier-free formulas. See the notes at the end of the section.)

The results of this section have to do with the relationship between PRA and subsystems of first order Peano arithmetic, PA. Our first task is to show that PRA is essentially included in $\Sigma^0_1$-PA (modulo a certain interpretation). For the definition of $\Sigma^0_1$-PA, see §IX.1.

DEFINITION IX.3.4. We define the *canonical interpretation* of the language of first order arithmetic, $L_1$, into the language of PRA. The constants 0 and 1 are interpreted as $\underline{0}$ and $\underline{1} \equiv \underline{S}(\underline{0})$ respectively. Addition and multiplication are interpreted as primitive recursive functions given by

$$x + \underline{0} = x, \qquad x + \underline{S}(y) = \underline{S}(x + y),$$
$$x \cdot \underline{0} = \underline{0}, \qquad x \cdot \underline{S}(y) = (x \cdot y) + x.$$

We introduce predecessor and truncated subtraction, $\underline{P}$ and $\dot{-}$, as primitive recursive functions given by

$$\underline{P}(\underline{0}) = \underline{0}, \qquad \underline{P}(\underline{S}(y)) = y,$$
$$x \dot{-} \underline{0} = x, \qquad x \dot{-} \underline{S}(y) = \underline{P}(x \dot{-} y).$$

We then interpret $t_1 < t_2$ as $t_2 \dot{-} t_1 \neq 0$.

LEMMA IX.3.5. *Any model of* $\Sigma_1^0$-PA *can be expanded to a model of* PRA *in a way which respects the canonical interpretation of* $\mathrm{L}_1$ *into the language of* PRA.

PROOF. By theorem IX.1.10, the given model of $\Sigma_1^0$-PA is the first order part of a model

$$M = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$

of $\mathsf{RCA}_0$. We can then use the results of §II.3 (particularly theorem II.3.4) to expand $M$ to a model of PRA. Namely, to each $k$-place primitive recursive function symbol $\underline{f}$ we associate a $k$-place function $f_M : |M|^k \to |M|$ such that $f_M \in \mathcal{S}_M$ and these functions obey the defining axioms as in definition IX.3.2 above. Under this interpretation, the PRA induction axioms follow from $\Sigma_1^0$ induction within $M$. Moreover, since the defining axioms for $+$, $\cdot$ and $<$ are theorems of $\mathsf{RCA}_0$, it is clear that $+$, $\cdot$, 0, 1 and $<$ are interpreted as $+_M$, $\cdot_M$, $0_M$, $1_M$ and $<_M$ respectively. This completes the proof. □

THEOREM IX.3.6. *Let* $\theta$ *be any* $\mathrm{L}_1$*-formula. If* $\theta$ *is provable in* PRA *under the canonical interpretation, then* $\theta$ *is provable in* $\Sigma_1^0$-PA (*hence also in* $\mathsf{RCA}_0$).

PROOF. Suppose that $\theta$ is not provable in $\Sigma_1^0$-PA. By the completeness theorem, let $(|M|, +_M, \cdot_M, 0_M, 1_M, <_M)$ be a model of $\Sigma_1^0$-PA in which $\theta$ fails. By the previous lemma, this can be expanded to a model of PRA in a way that respects the canonical interpretation of $\mathrm{L}_1$ into the language of PRA. Thus we have a model of PRA in which $\theta$ fails. Hence, by the soundness theorem, $\theta$ is not provable in PRA. This completes the proof of the theorem. □

Having shown that PRA is essentially included in $\Sigma_1^0$-PA, we now turn to the converse. We shall show that every $\Pi_2^0$ sentences which is provable in $\Sigma_1^0$-PA (indeed $\mathsf{WKL}_0$) is provable in PRA.

A formula in the language of PRA is said to be *generalized* $\Sigma_0^0$ if it is built from atomic formulas of the form $t_1 = t_2$ and $t_1 < t_2$, where $t_1$ and $t_2$ are terms in the language of PRA, by means of propositional connectives and bounded quantifiers of the form $(\forall x < t)$ and $(\exists x < t)$, where $t$ is a term in the language of PRA not mentioning $x$. The following lemma tells us that every generalized $\Sigma_0^0$ formula is equivalent to an atomic formula.

LEMMA IX.3.7. *For any generalized $\Sigma_0^0$ formula $\theta(x_1, \dots, x_k)$ with only the displayed free variables, we can find a $k$-place primitive recursive function symbol $\underline{f} = \underline{f}_\theta$ such that* PRA *proves*

(1) $\underline{f}(x_1, \dots, x_k) = \underline{1} \leftrightarrow \theta(x_1, \dots, x_k)$

*and*

(2) $\underline{f}(x_1, \dots, x_k) = \underline{0} \leftrightarrow \neg\theta(x_1, \dots, x_k)$.

PROOF. The proof is straightforward by induction on $\theta$. If $\theta \equiv \theta' \wedge \theta''$, we can take

$$\underline{f}_\theta(x_1, \dots, x_k) = \underline{f}_{\theta'}(x_1, \dots, x_k) \cdot \underline{f}_{\theta''}(x_1, \dots, x_k).$$

If $\theta(x_1, \dots, x_k) \equiv (\forall y < t)\, \theta'(y, x_1, \dots, x_k)$ where $t$ is a term whose free variables are among $x_1, \dots, x_k$, then we can take

$$\underline{f}_\theta(x_1, \dots, x_k) = \prod_{y<t} \underline{f}_{\theta'}(y, x_1, \dots, x_k).$$

Here $\underline{g}(z, x_1, \dots, x_k) = \prod_{y<z} \underline{f}_{\theta'}(y, x_1, \dots, x_k)$ is defined primitive recursively by

$$\underline{g}(\underline{0}, x_1, \dots, x_k) = 1,$$
$$\underline{g}(\underline{S}(z), x_1, \dots, x_k) = \underline{g}(z, x_1, \dots, x_k) \cdot \underline{f}_{\theta'}(z, x_1, \dots, x_k).$$

If $\theta \equiv \neg\theta'$, we can take

$$\underline{f}_\theta(x_1, \dots, x_k) = \underline{\mathrm{neg}}(\underline{f}_{\theta'}(x_1, \dots, x_k))$$

where $\underline{\mathrm{neg}}(\underline{0}) = \underline{1}$, $\underline{\mathrm{neg}}(\underline{S}(y)) = \underline{0}$. If $\theta$ is atomic of the form $t_1 = t_2$, we can take $\underline{f}_\theta(x_1, \dots, x_k) = \underline{\mathrm{neg}}((t_2 \dot{-} t_1) + (t_1 \dot{-} t_2))$. If $\theta$ is atomic of the form $t_1 < t_2$, we can take $\underline{f}_\theta(x_1, \dots, x_k) = \underline{\mathrm{neg}}(\underline{\mathrm{neg}}(t_2 \dot{-} t_1))$. The details of the verification that PRA proves (1) and (2) are left to the reader. □

For each $k$-place primitive recursive function symbol $\underline{f}$, we introduce a $k$-place *primitive recursive predicate symbol* $\underline{R} = \underline{R}_{\underline{f}}$ defined by

$$\underline{R}(x_1, \dots, x_k) \leftrightarrow \underline{f}(x_1, \dots, x_k) = \underline{1}.$$

In any model $M$ of PRA, $R_M$ is defined as the set of $k$-tuples $\langle a_1, \dots, a_k \rangle \in |M|^k$ such that $f_M(a_1, \dots, a_k) = 1_M$. The previous lemma implies that every generalized $\Sigma_0^0$ formula is equivalent to a primitive recursive predicate.

DEFINITION IX.3.8 ($M$-finite sets and $M$-cardinality). Let $M$ be a model of PRA.

1. An *$M$-finite set* is a set $X \subseteq |M|$ such that

$$X = \{a \in |M| : a <_M b \wedge R_M(a, c_1, \dots, c_k)\}$$

for some primitive recursive predicate symbol $\underline{R}$ and some parameters $b, c_1, \dots, c_k \in |M|$.

2. If $X$ is an $M$-finite set, the *$M$-cardinality of $X$* is the number of elements in $X$ as counted within $M$. Formally, the $M$-cardinality of $X$ is defined as $\mathrm{card}_M(X) = \mathrm{card}_M(X, b)$ where $X \subseteq \{a : a <_M b\}$ and

$$\mathrm{card}_M(X, 0) = 0,$$
$$\mathrm{card}_M(X, a+1) = \begin{cases} \mathrm{card}_M(X, a) + 1 & \text{if } a \in X, \\ \mathrm{card}_M(X, a) & \text{if } a \notin X. \end{cases}$$

In working with models of PRA, it will be important to know that $M$-finite sets can be *encoded* as single elements of $|M|$ in a primitive recursive way. There are several possible methods to accomplish this. For example, we could use the coding scheme of theorem II.2.5. Instead, we shall use the following method. We say that $c \in |M|$ *encodes* the $M$-finite set $X$ if

$$\forall a\, (a \in X \leftrightarrow M \models (\exists u < c)\, (\exists v < \underline{2}^a)\, (c = \underline{2}^{a+1} \cdot u + \underline{2}^a + v)).$$

Here the primitive recursive function $\underline{\exp}(x) = \underline{2}^x$ is defined by $\underline{\exp}(0) = 1$, $\underline{\exp}(\underline{S}(y)) = \underline{2} \cdot \underline{\exp}(y)$, where $\underline{2} = \underline{S}(\underline{1})$.

LEMMA IX.3.9. *Let $M$ be a model of* PRA. *Then for every $M$-finite set $X$, there is a unique $c \in |M|$ which encodes $X$. Furthermore $X \subseteq \{a : a <_M b\}$ if and only if $c <_M 2^b$.*

PROOF. The code of $X$ is $c = \sum_{a \in X} 2^a$. More formally, we define

$$c = \mathrm{code}_M(X) = \mathrm{code}_M(X, b)$$

where $X \subseteq \{a : a <_M \mathrm{b}\}$ and

$$\mathrm{code}_M(X, 0) = 0,$$
$$\mathrm{code}_M(X, a+1) = \begin{cases} \mathrm{code}_M(X, a) + 2^a & \text{if } a \in X, \\ \mathrm{code}_M(X, a) & \text{if } a \notin X. \end{cases}$$

It is straightforward to show within PRA that these codes have the desired properties. □

The concept of semiregular cut, defined below, is due to Kirby and Paris.

DEFINITION IX.3.10 (semiregular cuts). Let $M$ be a model of PRA.

1. A *cut* in $M$ is a set $I \subseteq |M|$, $1_M \in I \neq |M|$, such that $c <_M b, b \in I$ imply $c \in I$.
2. If $I$ is a cut in $M$, a set $X \subseteq I$ is said to be *$M$-coded* if there exists an $M$-finite set $X^*$ such that $X^* \cap I = X$. The set of all $M$-coded subsets of $I$ is denoted $\mathrm{Coded}_M(I)$. A set $X$ is said to be *bounded in $I$* if $X \subseteq \{a : a <_M b\}$ for some $b \in I$.
3. A cut $I$ is said to be *semiregular* if, for all $M$-finite sets $X$ such that $\mathrm{card}_M(X) \in I$, $X \cap I$ is bounded in $I$.

LEMMA IX.3.11. *Let $M$ be a model of* PRA, *and let $I$ be a semiregular cut in $M$. Then*

$$(I, \mathrm{Coded}_M(I), +_M \restriction I, \cdot_M \restriction I, 0_M, 1_M, <_M \restriction I) \tag{28}$$

*is a model of* $\mathsf{WKL}_0$.

Here $+_M \restriction I$ is the restriction of $+_M$ to $I$, etc.

PROOF. We first show that $I$ is closed under $+_M$ and $\cdot_M$. If $b, c \in I$ and $b +_M c \notin I$, then the $M$-finite set $X = \{a : b \leq_M a <_M b +_M c\}$ has $M$-cardinality $c$, yet $X \cap I = \{a \in I : b \leq_M a\}$ is unbounded in $I$, a contradiction. Thus $I$ is closed under $+_M$. Similarly, if $b, c \in I$ and $b \cdot_M c \notin I$, then the $M$-finite set $Y = \{b \cdot_M a : a <_M c\}$ has $M$-cardinality $c$, yet $Y \cap I$ is unbounded in $I$, a contradiction. Thus $I$ is closed under $\cdot_M$.

Since $M$ satisfies the primitive recursive induction scheme, every nonempty $M$-finite set has a $<_M$-least element. We shall now use this observation to show that the $\mathrm{L}_2$-structure (28) satisfies $\Sigma^0_1$ induction. Let $\varphi(x)$ be a $\Sigma^0_1$ formula with parameters from $I \cup \mathrm{Coded}_M(I)$ and no free variables other than $x$. We are trying to prove that (28) satisfies

$$(\varphi(0) \wedge \forall x\, (\varphi(x) \to \varphi(x+1))) \to \forall x\, \varphi(x). \tag{29}$$

If (28) satisfies $\varphi(c)$ for all $c \in I$, there is nothing to prove. So let $c \in I$ be such that (28) satisfies $\neg\varphi(c)$. Form the set

$$Y = \{a : a <_M c \text{ and (28) satisfies } \varphi(a)\}.$$

We claim that $Y$ is $M$-finite. To see this, let $\varphi^*(x)$ be the formula which results from $\varphi(x)$ when we replace each set parameter $X \in \mathrm{Coded}_M(I)$ by an $M$-finite set $X^*$ such that $X^* \cap I = X$. Thus we have $\varphi^*(x) \equiv \exists y\, \theta^*(x, y)$ where $\theta^*(x, y)$ is a generalized $\Sigma^0_0$ formula with parameters from $|M|$. Fix $d \in |M|$ such that $d \notin I$, and let $Z$ be the set of all pairs $(a, b)$ such that $a <_M c$, $b <_M d$, and $b$ is the $<_M$-least $b'$ such that $M$ satisfies $\theta^*(a, b')$. By lemma IX.3.7, $Z$ is $M$-finite. Moreover, the $M$-cardinality of $Z$ is at most $c$. Hence, by semiregularity, $Z \cap I$ is bounded in $I$. Hence $Z \cap I$ is $M$-finite. From this it follows (again by lemma IX.3.7) that $Y = \{a : \exists b\, ((a, b) \in Z \cap I)\}$ is $M$-finite. This proves our claim.

Since $Y$ is $M$-finite and $c \notin Y$, let $b$ be the $<_M$-least element of $I$ such that $b \notin Y$. If $b = 0_M$ we see that (28) satisfies $\neg\varphi(0)$. If $b = S_M(b')$, we see that (28) satisfies $\varphi(b')$ and $\neg\varphi(b' + 1)$. In either case, (28) satisfies (29). We have now shown that (28) satisfies $\Sigma^0_1$ induction.

Next we shall show that (28) satisfies the $\Sigma^0_1$ separation principle IV.4.4.2. Let $\varphi_i(x)$, $i \in \{0, 1\}$ be $\Sigma^0_1$ formulas with parameters from $I \cup \mathrm{Coded}_M(I)$ and no free variables other than $x$. For $i \in \{0, 1\}$ put

$$A_i = \{a \in I : (28) \text{ satisfies } \varphi_i(a)\}$$

and assume that $A_0 \cap A_1 = \emptyset$. We must show that $A_0$ and $A_1$ can be separated by an $M$-coded subset of $I$. Let $\varphi_i^*(x)$ be the formula which results from $\varphi_i(x)$ when we replace each set parameter $X \in \mathrm{Coded}_M(I)$ by an $M$-finite set $X^*$ such that $X^* \cap I = X$. As before, we have $\varphi_i^*(x) \equiv \exists y\, \theta_i^*(x, y)$ where $\theta_i^*(x, y)$ is a generalized $\Sigma_0^0$ formula with parameters from $|M|$. Fix $d \in |M|$ such that $d \notin I$, and put

$$Y^* = \{a : a <_M d \wedge (\exists b <_M d)\,(\theta_1^*(a, b) \wedge (\forall b' <_M b)\,\neg\theta_0^*(a, b'))\}.$$

Clearly $A_1 \subseteq Y^*$ and $Y^* \cap A_0 = \emptyset$. Moreover, by lemma IX.3.7, $Y^*$ is $M$-finite. Putting $Y = Y^* \cap I$, we see that $Y$ is an $M$-coded subset of $I$ which separates $A_0$ and $A_1$. Thus (28) satisfies $\Sigma_1^0$ separation.

Obviously $\Sigma_1^0$ separation implies $\Delta_1^0$ comprehension. Hence (28) is a model of $\mathsf{RCA}_0$. By lemma IV.4.4, it follows that (28) is a model of $\mathsf{WKL}_0$. This completes the proof of lemma IX.3.11. □

DEFINITION IX.3.12. Let $M$ be a model of PRA. For $b, c \in |M|$, we write $b \ll_M c$ to mean that $f_M(b) <_M c$ for all 1-place primitive recursive function symbols $\underline{f}$.

LEMMA IX.3.13 (existence of semiregular cuts). *Let $M$ be a countable model of* PRA. *Suppose that $b, c \in |M|$ are such that $b \ll_M c$. Then there exists a semiregular cut $I$ in $M$ such that $b \in I$ and $c \notin I$.*

PROOF. For any finite interval $[b, c) = \{i : b \leq i < c\}$ of nonnegative integers, we define a concept of *$n$-bigness*, by recursion on $n$. We say that $[b, c)$ is 0-big if $b < c$. We say that $[b, c)$ is $(n+1)$-big if for every finite set $X$ of cardinality $\leq b$, there exist $b'$ and $c'$ such that $b < b' < c' < c$ and $[b', c')$ is $n$-big and disjoint from $X$.

The definition of $n$-bigness can be carried out within PRA. Formally, we have a primitive recursive predicate $\underline{B}(x, y, z)$, meaning that the interval $[y, z)$ is $x$-big, defined by recursion on $x$. We have $\underline{B}(0, y, z) \leftrightarrow y < z$, and $\underline{B}(\underline{S}(x), y, z) \leftrightarrow$ for all $w < \underline{2}^z$, if the finite set $X$ encoded by $w$ is of cardinality $\leq y$, then there exist $y'$ and $z'$ such that $y < y' < z' < z$ and $\underline{B}(x, y', z')$ and $\forall u\,(y' \leq u < z' \rightarrow u \notin X)$. (We are using definition IX.3.8 and lemmas IX.3.7 and IX.3.9, above.)

Also within PRA we have, for each standard nonnegative integer $n < \omega$, a 1-place primitive recursive function symbol $\underline{g}_n$ with defining axioms

$$\underline{g}_0(y) = y + 1,$$
$$\underline{g}_{n+1}(y) = \underbrace{\underline{g}_n \underline{g}_n \cdots \underline{g}_n}_{y+1}(y + 1) + 1.$$

For each $n < \omega$, we can then prove within PRA that, for all $y$ and $z$, $\underline{g}_n(y) \leq z$ implies $\underline{B}(\underline{n}, y, z)$. Here $\underline{n}$ is the constant term $\underline{S} \cdots \underline{S}(\underline{0})$, with $n$ occurrences of $\underline{S}$.

Now let $M$ be a countable model of PRA. As in the hypothesis of our lemma, let $b, c \in |M|$ be such that $f_M(b) <_M c$ for all 1-place primitive recursive functions symbols $f$. In particular, for each standard nonnegative integer $n < \omega$, we have $g_n^M(b) <_M c$, hence $B_M(n, b, c)$ holds. On the other hand, it is clear that $B_M(\alpha, b, c)$ does not hold for all $\alpha \in |M|$, so let $v$ be the $<_M$-largest element of $|M|$ such that $B_M(v, b, c)$ does hold. Then for all standard $n$ we have $n <_M v$.

Since $M$ is countable, the set of $M$-finite sets is countable, so let $\langle X_n : n < \omega \rangle$ be an enumeration of these sets. We may assume that each $M$-finite set occurs infinitely many times in this enumeration. We shall inductively define sequences

$$b = b_0 <_M b_1 <_M \cdots <_M b_n <_M \cdots$$

and

$$c = c_0 >_M c_1 >_M \cdots >_M c_n >_M \cdots,$$

as follows. Begin with $b_0 = b$ and $c_0 = c$. If $\mathrm{card}_M(X_0) \geq_M b_0$, set $b_1 = b_0 + 1$ and $c_1 = c_0 - 1$. If $\mathrm{card}_M(X_0) <_M b_0$, then since $M \models [b_0, c_0)$ is $v$-big, we can find $b_1$ and $c_1$ such that $b_0 <_M b_1 <_M c_1 <_M c_0$ and $M \models [b_1, c_1)$ is $(v-1)$-big and disjoint from $X_0$. Suppose now that $b_n$ and $c_n$ have been defined. If $\mathrm{card}_M(X_n) \geq_M b_n$, set $b_{n+1} = b_n + 1$ and $c_{n+1} = c_n - 1$. If $\mathrm{card}_M(X_n) <_M b_n$, then since $M \models [b_n, c_n)$ is $(v-n)$-big, we can find $b_{n+1}$ and $c_{n+1}$ such that $b_n <_M b_{n+1} <_M c_{n+1} <_M c_n$ and $M \models [b_{n+1}, c_{n+1})$ is $(v-n-1)$-big and disjoint from $X_n$.

Finally, let $I$ be the set of $a \in |M|$ such that $a <_M b_n$ for some $n < \omega$. We claim that $I$ is a semiregular cut. To see this, let $X$ be an $M$-finite set such that $\mathrm{card}_M(X) \in I$. Since $X = X_n$ for infinitely many $n$, we can find $n$ such that $X = X_n$ and $\mathrm{card}_M(X) <_M b_n$. Then by construction $M \models [b_{n+1}, c_{n+1})$ is disjoint from $X$. Hence $X \cap I \subseteq \{a : a <_M b_{n+1}\}$, so $X \cap I$ is bounded in $I$.

This completes the proof of lemma IX.3.13. □

EXERCISE IX.3.14. Let the primitive recursive function symbols $\underline{g}_n$, $n \in \omega$, be as in the proof of lemma IX.3.13. Show that, for each 1-place primitive recursive function symbol $\underline{f}$, we can find $n < \omega$ such that $\forall x\, (\underline{f}(x) \leq \underline{g}_n(x))$ is provable in PRA.

EXERCISE IX.3.15. Let $M$ be a countable model of PRA, and let $b, c \in |M|$ be given. Show that $b \ll_M c$ if and only if there exists a semiregular cut $I$ in $M$ such that $b \in I$ and $c \notin I$. Show that if $b \ll_M c$ and $X$ is $M$-finite with $\mathrm{card}_M(X) <_M b$, then there exist $b'$ and $c'$ such that $b <_M b' \ll_M c' <_M c$ and $\{a : b' \leq_M a <_M c'\}$ is disjoint from $X$.

THEOREM IX.3.16 (conservation theorem). *Let $\psi$ be a $\Pi_2^0$ sentence. If $\psi$ is provable in* $\mathsf{WKL}_0$, *then $\psi$ is provable in* PRA (*under the canonical interpretation of* $\mathsf{L}_1$ *into the language of* PRA).

Proof. Suppose that $\psi$ is not provable in PRA. By Gödel's completeness theorem, there is a countable model $M'$ of PRA in which $\psi$ is false. Writing $\psi \equiv \forall y\, \exists z\, \theta(y,z)$ where $\theta(y,z)$ is $\Sigma^0_0$, let $b' \in |M'|$ be such that $M' \models \neg\exists z\, \theta(b',z)$.

We now introduce two new constant symbols $\underline{b}$ and $\underline{c}$ and consider the theory $T$ whose axioms are those of PRA, plus $\neg\exists z\, \theta(\underline{b},z)$, plus $\underline{f}(\underline{b}) < \underline{c}$ for all 1-place primitive recursive function symbols $\underline{f}$. For any finite subset $T_0$ of the axioms of $T$, we can choose an element $c'_0 \in |M'|$ such that $f_{M'}(b) <_{M'} c'_0$ for all of the finitely many 1-place primitive recursive function symbols $\underline{f}$ which are mentioned in $T_0$. Thus $M' \models T_0$ with $\underline{b}$ and $\underline{c}$ interpreted as $b'$ and $c'_0$. This shows that each finite subset of the axioms of $T$ has a countable model. Hence, by the compactness theorem, $T$ has a countable model.

This means that we have a countable model $M$ of PRA and elements $b, c \in |M|$ such that $b \ll_M c$ and $M \models \neg\exists z\, \theta(b,z)$. By lemma IX.3.13, there is a semiregular cut $I$ in $M$ such that $b \in I$ and $c \notin I$. By lemma IX.3.11,

$$(I, \mathrm{Coded}_M(I), +_M \restriction I, \cdot_M \restriction I, 0_M, 1_M, <_M \restriction I) \tag{30}$$

is a model of $\mathsf{WKL}_0$. It is also clear that (30) satisfies $\neg\exists z\, \theta(b,z)$, hence (30) satisfies $\neg\psi$. Hence, by the soundness theorem, $\psi$ is not provable in $\mathsf{WKL}_0$. This completes the proof of theorem IX.3.16. □

Remark IX.3.17 (equiconsistency of PRA and $\mathsf{WKL}_0$). Using the methods of §§II.8 and IV.3, the previous theorem can be proved in $\mathsf{WKL}_0$ and hence in PRA. Thus $\mathsf{WKL}_0$ and PRA have the same consistency strength.

Remark IX.3.18 (Hilbert's program). The results of this section shed considerable light on a very important direction of research in the foundations of mathematics, known as *Hilbert's program* or, more descriptively, *finitistic reductionism*. Hilbert was the foremost mathematician of his time, and his ideas about the "problem of infinity" in the foundations of mathematics are of great interest. We here limit ourselves to a very brief discussion.

Hilbert assigned a special role to a certain restricted kind of mathematical reasoning, known as *finitistic*. Roughly speaking, finitism is that part of mathematics which rejects completed infinite totalities and is indispensable for all scientific reasoning. For example, finitism is adequate for elementary reasoning about strings of symbols, but it is not adequate for reasoning about arbitrary sets of integers. Hilbert never spelled out a precise definition of finitism, but it is generally agreed that the formal system PRA (definition IX.3.2 above) captures this notion.

The essence of Hilbert's program was to show that non-finitistic, set-theoretical mathematics can be reduced to finitism. The reduction was to

be accomplished by means of finitistic consistency proofs or, somewhat more generally, by means of conservation results for $\Pi^0_1$ sentences.

Unfortunately, Gödel's incompleteness theorems [94, 115, 55, 222] imply that a wholesale realization of Hilbert's program is impossible. There is no hope of proving the consistency of set theory within PRA, nor is there any hope of showing that set theory is conservative over PRA for $\Pi^0_1$ sentences.

In view of Gödel's limitative results, it is of interest to ask what part of Hilbert's program can be carried out. In other words, which portions of infinitistic mathematics can be reduced to finitism? The study of subsystems of second order arithmetic makes it possible to give a more precise formulation of this question: *Which interesting subsystems of* $\mathsf{Z}_2$ *are conservative over* PRA *for* $\Pi^0_1$ *sentences*? In this context, a subsystem of $\mathsf{Z}_2$ is considered interesting if it accommodates the development of a large part of mathematical practice.

Thus, theorem IX.3.16 emerges as a key result toward a partial realization of Hilbert's program. Theorem IX.3.16 shows that $\mathsf{WKL}_0$ is conservative over PRA for $\Pi^0_1$ sentences (in fact $\Pi^0_2$ sentences). This conservation result, together with the results of chapters II and IV concerning the development of mathematics within $\mathsf{WKL}_0$, implies that a significant part of mathematical practice is finitistically reducible, in the precise sense envisioned by Hilbert.

For example, all of the following key theorems of infinitistic mathematics are provable in $\mathsf{WKL}_0$ and therefore, by theorem IX.3.16, reducible to finitism. (1) The Heine/Borel covering theorem for closed bounded subsets of $\mathbb{R}^n$ or for closed subsets of any compact metric space. (2) Basic properties of continuous real-valued functions of several real variables. (3) The local existence theorem for solutions of ordinary differential equations. (4) The Hahn/Banach theorem in separable Banach spaces. (5) The existence theorem for prime ideals in countable commutative rings. (6) Existence and uniqueness of the algebraic closure of a countable field. (7) Orderability and existence of the real closure of a countable formally real field.

To summarize, $\mathsf{WKL}_0$ embodies a significant and far-reaching partial realization of Hilbert's program of finite reductionism.

**Notes for §IX.3.** For a thorough introduction to primitive recursive functions, see Kleene [142]. In connection with exercise IX.3.14, note that the functions $g_n$, $n < \omega$, are essentially the "branches" of the Ackermann function; see also Robinson [207].

The formal system PRA is of fundamental importance for the foundations of mathematics, being the formal analog of Hilbert's informal notion of finitistic provability. See Hilbert [114], Feferman [55], and Tait [259].

The model-theoretic result of Tarski, referred to in the hint for exercise IX.3.3, can be found in any model theory textbook, e.g., Chang/Keisler [35] or Sacks [210].

Parsons [201] used a functional interpretation to show that every $\Pi^0_2$ sentence provable in $\Sigma^0_1$-PA is provable in PRA. Theorem IX.3.16 may be viewed as a consequence of this theorem of Parsons plus Harrington's result in §IX.2 above. Theorem IX.3.16 is due to Friedman (1976, unpublished). The idea of the model-theoretic proof of theorem IX.3.16, which we have given here, is from Kirby/Paris [140]. Another proof of theorem IX.3.16, via Gentzen-style proof theory, has been given by Sieg [225]. For a fuller discussion of the relationship between Hilbert's program and theorem IX.3.16, see Simpson [246].

## IX.4. Saturated Models

In §VII.6 we obtained some conservation theorems involving versions of the axiom of choice in the language of $\mathsf{Z}_2$. In this section we shall prove some more results of this kind. We shall prove: (1) $\Sigma^1_1$-$\mathsf{AC}_0$ is conservative over $\mathsf{ACA}_0$ for $\Pi^1_2$ sentences; (2) $\Sigma^1_2$-$\mathsf{AC}_0$ is conservative over $\Pi^1_1$-$\mathsf{CA}_0$ for $\Pi^1_3$ sentences; (3) for all $k < \omega$, $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ is conservative over $\Pi^1_{k+2}$-$\mathsf{CA}_0$ for $\Pi^1_4$ sentences. These results depend essentially on the use of non-$\omega$-models. Specifically, our proofs employ a model-theoretic concept known as *saturation*.

DEFINITION IX.4.1 (saturated models). The following concepts are defined in $\mathsf{RCA}_0$. Let $L$ be a countable first order language, and let $M$ be a countable model for $L$ (in the sense of definition II.8.3).

1. A 1-*type over* $M$ is a sequence of formulas $\langle \varphi_i(x, b_1, \dots, b_k) : i \in \mathbb{N} \rangle$ with a finite set of parameters $b_1, \dots, b_k \in |M|$ and no free variables other than $x$, such that
$$\forall j \, (\exists a \in |M|) \, (\forall i \leq j) \, M \models \varphi_i(a, b_1, \dots, b_k).$$
This 1-type is said to be *realized in* $M$ if
$$(\exists a \in |M|) \, \forall i \, M \models \varphi_i(a, b_1, \dots, b_k).$$
2. A 1-type as above is said to be $X$-*recursive*, where $X \subseteq \mathbb{N}$, if the sequence of $L$-formulas $\langle \varphi_i(x, y_1, \dots, y_k) : i \in \mathbb{N} \rangle$ is $X$-recursive.
3. We say that $M$ is $X$-*recursively saturated* if every $X$-recursive 1-type over $M$ is realized in $M$. We say that $M$ is *recursively saturated* if it is $\emptyset$-recursively saturated.

LEMMA IX.4.2 (existence of saturated models). *Let $L$ be a countable first order language. Let $S$ be a consistent set of $L$-sentences. Then for any $X \subseteq \mathbb{N}$ there exists a countable $X$-recursively saturated model of $S$. This result is provable in* $\mathsf{WKL}_0$.

PROOF. We reason in $\mathsf{WKL}_0$. We shall employ a variant of the Henkin construction which was already used in §§II.8 and IV.3.

We consider an expanded language $L(C) = L \cup C$ where $C$ is a countably infinite set of new constant symbols. We call a sequence $\langle \varphi_i(x) : i \in \mathbb{N} \rangle$ of $L(C)$-formulas *acceptable* if it has only the free variable $x$ and mentions only finitely many of the constant symbols in $C$. Fix a one-to-one enumeration $\langle \underline{c}_n : n \in \mathbb{N} \rangle$ of $C$. Fix an enumeration $\langle \langle \varphi_{ni}(x) : i \in \mathbb{N} \rangle : n \in \mathbb{N} \rangle$ of all $X$-recursive acceptable sequences of $L(C)$-formulas. We may safely assume that $\varphi_{ni}(x)$ does not mention any $\underline{c}_m$, $m \geq n$. Let $S(C)$ be the set of $L(C)$-sentences consisting of $S$ plus Henkin axioms

$$(\exists x\, (\varphi_{n0}(x) \wedge \cdots \wedge \varphi_{nj}(x))) \rightarrow (\varphi_{n0}(\underline{c}_n) \wedge \cdots \wedge \varphi_{nj}(\underline{c}_n))$$

for all $n$ and $j$. A syntactical argument from the consistency of $S$ shows that $S(C)$ is consistent. By Lindenbaum's lemma in $\mathsf{WKL}_0$ (theorem IV.3.3), let $S(C)^*$ be a completion of $S(C)$. As in the proof of theorem II.8.4, we can read off a countable $L$-model $M$ from $S(C)^*$. By construction, $M$ satisfies $S$ and is $X$-recursively saturated. This completes the proof of lemma IX.4.2. □

The main results of this section will be obtained by applying lemma IX.4.2 to sets of sentences in the countable first order language $\mathrm{L}_1(\underline{A})$ consisting of $\mathrm{L}_1$, the language of first order arithmetic, plus countably many 1-place predicate symbols $\underline{A}_n$, $n \in \omega$. We shall usually treat $\underline{A}_n$ as a set constant, writing $t \in \underline{A}_n$ instead of the more orthodox $\underline{A}_n(t)$. Thus the formulas of $\mathrm{L}_1(\underline{A})$ are built up by means of propositional connectives and number quantifiers from atomic formulas $t_1 = t_2$, $t_1 < t_2$, and $t_1 \in \underline{A}_n$, where $t_1$ and $t_2$ are numerical terms. An $\mathrm{L}_1(\underline{A})$-structure $M$ consists of an $\mathrm{L}_1$-structure $(|M|, +_M, \cdot_M, 0_M, 1_M, <_M)$ together with sets $A_n^M \subseteq |M|$, $n \in \omega$. Here of course $A_n^M$ is used to interpret $\underline{A}_n$.

If $M$ is an $\mathrm{L}_1(\underline{A})$-structure, the associated $\mathrm{L}_2$-structure is

$$M_2 = (|M|, \mathcal{S}_M, +_M, \cdot_M, 0_M, 1_M, <_M)$$

where $\mathcal{S}_M$ consists of all subsets of $|M|$ of the form

$$(A_n^M)_b = \{a \in |M| : M \models (a, b) \in \underline{A}_n\}$$

with $n \in \omega$, $b \in |M|$.

LEMMA IX.4.3. *Let $M$ be a recursively saturated $\mathrm{L}_1(\underline{A})$-model which satisfies the basic axioms* I.2.4(i), *induction for all $\Sigma^0_1$ formulas in the language $\mathrm{L}_1(\underline{A})$, and the axioms $\mathsf{TJ}(\underline{A}_n) = \underline{A}_{n+1}$ for all $n \in \mathbb{N}$. Then the associated $\mathrm{L}_2$-structure $M_2$ satisfies $\Sigma^1_1$-$\mathsf{AC}_0$. This result is provable in $\mathsf{ACA}_0$.*

PROOF. Note first that $M_2$ is a model of $\mathsf{ACA}_0$. (See §VIII.1 for a discussion of the relationship between $\mathsf{ACA}_0$ and the Turing jump operator TJ.)

Assume now that $M_2$ satisfies $\forall x\, \exists Y\, \eta(x, Y)$ where $\eta(x, Y)$ is a $\Sigma^1_1$ formula with parameters from $|M| \cup \mathcal{S}_M$. Let us write $\eta(x, Y) \equiv \exists Z\, \theta(x, Y, Z)$

where $\theta$ is arithmetical with parameters from $|M| \cup \mathcal{S}_M$. Thus $M_2$ satisfies $\forall x\, \exists Y\, \exists Z\, \theta(x, Y, Z)$. Here $x$ is a number variable while $Y$ and $Z$ are set variables.

We claim that, for some $n$, $M$ satisfies

$$\forall x\, \exists y\, \exists z\, \theta(x, (\underline{A}_n)_y, (\underline{A}_n)_z).$$

If not, then we have a recursive 1-type consisting of the formulas

$$\neg\exists y\, \exists z\, \theta(x, (\underline{A}_n)_y, (\underline{A}_n)_z)$$

for all $n$. By recursive saturation, there exists $a \in |M|$ such that for all $n$, $M$ satisfies $\neg\exists y\, \exists z\, \theta(a, (\underline{A}_n)_y, (\underline{A}_n)_z)$. This implies that $M_2$ satisfies

$$\neg\exists Y\, \exists Z\, \theta(a, Y, Z),$$

a contradiction. Our claim is proved.

From the above claim, we see that

$$M_2 \models \exists W\, \forall x\, \exists y\, \exists z\, \theta(x, (W)_y, (W)_z).$$

Since $M_2$ is a model of $\mathsf{ACA}_0$, it follows that

$$M_2 \models \exists W\, \forall x\, \eta(x, (W)_x).$$

Thus $M_2$ is a model of $\Sigma^1_1$ choice. The proof of lemma IX.4.3 is complete. □

The following theorem stands in contrast to the results of chapter VIII, according to which the minimum $\omega$-model of $\mathsf{ACA}_0$ is the class ARITH of arithmetical sets, while the minimum $\omega$-model of $\Sigma^1_1$-$\mathsf{AC}_0$ (or of $\Delta^1_1$-$\mathsf{CA}_0$) is the much larger class HYP of hyperarithmetical sets.

THEOREM IX.4.4 (conservation theorem). $\Sigma^1_1$-$\mathsf{AC}_0$ (*hence also* $\Delta^1_1$-$\mathsf{CA}_0$) *is conservative over* $\mathsf{ACA}_0$ *for* $\Pi^1_2$ *sentences. In other words, any* $\Pi^1_2$ *sentence which is provable in* $\Sigma^1_1$-$\mathsf{AC}_0$ *is already provable in* $\mathsf{ACA}_0$.

PROOF. Let $\psi$ be a $\Pi^1_2$ sentence which is not provable in $\mathsf{ACA}_0$. By Gödel's completeness theorem, let $M'$ be a model of $\mathsf{ACA}_0$ in which $\psi$ is false. Writing $\psi \equiv \forall X\, \exists Y\, \theta(X, Y)$ where $\theta(X, Y)$ is arithmetical, choose $A' \in \mathcal{S}_{M'}$ such that $M' \models \neg\exists Y\, \theta(A', Y)$. Define a sequence of elements $A'_n \in \mathcal{S}_{M'}$, $n \in \omega$, where $A'_0 = A'$ and for all $n$, $A'_{n+1}$ is the unique $B \in \mathcal{S}_{M'}$ such that $M' \models B = \mathrm{TJ}(A'_n)$. The first order part of $M'$ together with the sets $A'_n$, $n \in \omega$, form an $\mathrm{L}_1(\underline{A})$-structure. Clearly this structure satisfies the axioms mentioned in lemma IX.4.3, plus additional axioms $\neg\exists y\, \theta(\underline{A}_0, (\underline{A}_n)_y)$ for all $n \in \omega$. Hence, by lemma IX.4.2, there exists a recursively saturated model $M$ of these axioms. By lemma IX.4.3, the associated $\mathrm{L}_2$-structure $M_2$ satisfies $\Sigma^1_1$-$\mathsf{AC}_0$. It is also clear that $M_2$ satisfies $\neg\exists Y\, \theta(\underline{A}_0, Y)$, hence $M_2$ satisfies $\neg\psi$. Therefore, by the soundness theorem, $\psi$ is not provable in $\Sigma^1_1$-$\mathsf{AC}_0$. Also, it follows by lemma VII.6.6 that $\psi$ is not provable in $\Delta^1_1$-$\mathsf{CA}_0$. This completes the proof of theorem IX.4.4. □

As another interesting application of the above ideas, we present the following result. For any recursively axiomatizable $L_2$-theory $T_0$, $\Pi^1_{k+1}$ *correctness of* $T_0$ is the assertion that every $\Pi^1_{k+1}$ sentence provable in $T_0$ is true. (This assertion is formalized by means of a universal $\Pi^1_{k+1}$ formula.)

THEOREM IX.4.5.

1. $\mathsf{ACA}_0$ *plus* $\Sigma^1_1$-$\mathsf{IND}$ *proves* $\Pi^1_2$ *correctness of* $\Sigma^1_1$-$\mathsf{AC}_0$.
2. $\Sigma^1_1$-$\mathsf{AC}_0$ *plus* $\Sigma^1_1$-$\mathsf{IND}$ *proves* $\Pi^1_3$ *correctness of* $\Sigma^1_1$-$\mathsf{AC}_0$.

PROOF. In order to prove 1, we reason in $\mathsf{ACA}_0$ plus $\Sigma^1_1$-$\mathsf{IND}$. We are going to show that every $\Pi^1_2$ sentence provable in $\Sigma^1_1$-$\mathsf{AC}_0$ is true. Let $\psi$ be a $\Pi^1_2$ sentence which is not true. Writing $\psi \equiv \forall X\, \exists Y\, \theta(X, Y)$ where $\theta(X, Y)$ is arithmetical, fix $A_0 \subseteq \mathbb{N}$ such that $\neg\exists Y\, \theta(A_0, Y)$ holds. Let $S$ be the set of $L_1(\underline{A})$-sentences mentioned in lemma IX.4.3 plus additional axioms $\neg\exists y\, \theta(\underline{A}_0, (\underline{A}_n)_y)$, for all $n$. Let $S_n$ consist of $S$ restricted to the language $L_1 \cup \{\underline{A}_0, \ldots, \underline{A}_n\}$. By arithmetical comprehension plus $\Sigma^1_1$ induction on $n$, we have

$$\forall n\, \exists W((W)_0 = A_0 \wedge (\forall i < n)\, \mathrm{TJ}((W)_i) = (W)_{i+1}).$$

It follows that for all $n$ there exists an $\omega$-model of $S_n$. Hence, by the strong soundness theorem, we have that for all $n$, $S_n$ is consistent. (Concerning the strong soundness theorem, see lemma VII.2.2 and theorem II.8.10.) Hence $S$ is consistent. Arguing as in the proof of theorem IX.4.4, we conclude that $\psi$ is not provable in $\Sigma^1_1$-$\mathsf{AC}_0$. This establishes part 1 of our theorem.

In order to prove part 2, we shall need the following variant of lemma IX.4.3. Let $\pi(e, m_1, X_1)$ be a universal lightface $\Pi^0_1$ formula, as in the definition of Turing jump (definition VIII.1.9). Then lemma IX.4.3 holds if we replace

$$\mathrm{TJ}(\underline{A}_n) = \underline{A}_{n+1}$$

by the weaker condition

$$\forall i\, \exists j\, \forall m\, (\pi(i, m, \underline{A}_n) \leftrightarrow m \in (\underline{A}_{n+1})_j).$$

The proof is the same as for lemma IX.4.3.

Now, reasoning in $\Sigma^1_1$-$\mathsf{AC}_0$ plus $\Sigma^1_1$-$\mathsf{IND}$, we are going to show that any $\Pi^1_3$ sentence provable in $\Sigma^1_1$-$\mathsf{AC}_0$ is true. Let $\psi$ be a $\Pi^1_3$ sentence which is not true. Writing $\psi \equiv \forall X\, \exists Y\, \forall Z\, \theta(X, Y, Z)$ where $\theta(X, Y, Z)$ is arithmetical, fix $A_0 \subseteq \mathbb{N}$ such that

$$\forall Y\, \exists Z\, \neg\theta(A_0, Y, Z)$$

holds. Let $\varphi(X, Y, Z)$ be the arithmetical formula

$$\forall i\, \exists j\, \forall m\, (\pi(i, m, Y) \leftrightarrow m \in (Z)_j) \wedge \forall i\, \exists j\, \neg\theta(X, (Y)_i, (Z)_j).$$

Let $S$ be the set of $L_1(\underline{A})$-sentences consisting of the basic axioms I.2.4(i), induction for all $\Sigma^0_1$ formulas of $L_1(\underline{A})$, and $\varphi(\underline{A}_0, \underline{A}_n, \underline{A}_{n+1})$ for all $n$. We

are going to show that $S$ is consistent. Let $S_n$ consist of $S$ restricted to $L_1 \cup \{\underline{A}_0, \ldots, \underline{A}_n\}$. By arithmetical comprehension and $\Sigma^1_1$ choice, we have $\forall Y\, \exists Z\, \varphi(A_0, Y, Z)$. Hence, by $\Sigma^1_1$ induction on $n$, we have

$$\forall n\, \exists W\, ((W)_0 = A_0 \wedge (\forall i < n)\, \varphi(A_0, (W)_i, (W)_{i+1})).$$

Thus we see that for all $n$ there exists an $\omega$-model of $S_n$. Hence by the strong soundness theorem, $S$ is consistent. By lemma IX.4.2, there exists a recursively saturated model $M$ of $S$. Let $M_2$ be the associated $L_2$-structure. By the above-mentioned variant of lemma IX.4.3, $M_2$ satisfies $\Sigma^1_1$-$\mathsf{AC}_0$. It is also clear that $M_2$ satisfies $\forall Y\, \exists Z\, \neg\theta(\underline{A}_0, Y, Z)$, hence $M_2$ satisfies $\neg\psi$. Hence $\psi$ is not provable in $\Sigma^1_1$-$\mathsf{AC}_0$. This establishes part 2.

The proof of theorem IX.4.5 is complete. □

COROLLARY IX.4.6 (consistency of $\Sigma^1_1$-$\mathsf{AC}_0$). $\mathsf{ACA}_0$ *plus* $\Sigma^1_1$-IND *proves the consistency of* $\Sigma^1_1$-$\mathsf{AC}_0$.

PROOF. This follows by applying part 1 of theorem IX.4.5 to the sentence $1 = 0$. □

COROLLARY IX.4.7. $\mathsf{ATR}_0$ *plus* $\Sigma^1_1$-IND *proves the consistency of* $\mathsf{ATR}_0$. *It follows that* $\Sigma^1_1$-IND *is not provable in* $\mathsf{ATR}_0$.

(Compare lemma VIII.6.15.)

PROOF. We reason in $\mathsf{ATR}_0$ plus $\Sigma^1_1$-IND. Recall that $\mathsf{ATR}_0$ can be axiomatized by $\Sigma^1_1$-$\mathsf{AC}_0$ plus a single $\Pi^1_2$ sentence $\psi$ (see theorem VIII.3.15). If $\mathsf{ATR}_0$ were inconsistent, then $\Sigma^1_1$-$\mathsf{AC}_0$ would prove $\neg\psi$. Hence, by $\Pi^1_3$ soundness of $\Sigma^1_1$-$\mathsf{AC}_0$ (part 2 of theorem IX.4.5), $\neg\psi$ would be true, a contradiction. This proves the first sentence of our corollary. The second sentence follows by Gödel's second incompleteness theorem [94, 115, 55, 222]. □

For the next lemma, let $k < \omega$ be fixed.

LEMMA IX.4.8. *Let $M$ be a recursively saturated $L_1(\underline{A})$-model which satisfies the basic axioms* I.2.4(i) *plus arithmetical induction (i.e., induction for all $L_1(\underline{A})$-formulas) plus "the countable $\omega$-model encoded by $\underline{A}_{n+1}$ contains $\underline{A}_n$ as an element, satisfies* $\mathsf{ACA}_0$, *and is a $\beta_{k+1}$-submodel of the countable $\omega$-model encoded by $\underline{A}_{n+2}$," for all $n$. Then the associated $L_2$-structure $M_2$ satisfies strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+2}$-$\mathsf{AC}_0$. This result is provable in* $\mathsf{ACA}_0$.

PROOF. Clearly $M_2$ satisfies $\mathsf{ACA}_0$ and, for each $n \in \omega$,

$$M_2 \models \text{ the countable } \omega\text{-model encoded by } \underline{A}_{n+1} \text{ is a } \beta_{k+1}\text{-model.} \quad (31)$$

Hence, by theorem VII.7.4, $M_2$ satisfies strong $\Sigma^1_{k+1}$-$\mathsf{DC}_0$.

Assume now that $M_2$ satisfies $\forall x\, \exists Y\, \eta(x, Y)$ where $\eta(x, Y)$ is a $\Sigma^1_{k+2}$ formula with parameters from $|M| \cup \mathcal{S}_M$. Let us write $\eta(x, Y) \equiv \exists Z\, \psi(x, Y, Z)$ where $\psi$ is $\Pi^1_{k+1}$. Thus $M_2$ satisfies $\forall x\, \exists Y\, \exists Z\, \psi(x, Y, Z)$. (Here $x$ is a number variable while $Y$ and $Z$ are set variables.) This implies that

$$(\forall a \in |M|)\, \exists n\, M_2 \models \exists y\, \exists z\, \psi(a, (\underline{A}_{n+1})_y, (\underline{A}_{n+1})_z).$$

Hence by (31) it follows that

$$(\forall a \in |M|)\, \exists n\, M \models \text{ the countable } \omega\text{-model coded by } \underline{A}_{n+1} \text{ satisfies } \exists y\, \exists z\, \psi(a, (\underline{A}_{n+1})_y, (\underline{A}_{n+1})_z).$$

By recursive saturation, there exists $n \in \omega$ such that

$$(\forall a \in |M|)\, M \models \text{ the countable } \omega\text{-model coded by } \underline{A}_{n+1} \text{ satisfies } \exists y\, \exists z\, \psi(a, (\underline{A}_{n+1})_y, (\underline{A}_{n+1})_z).$$

By (31) plus arithmetical comprehension within $M_2$, it follows that that $M_2 \models \exists W\, \forall x\, \psi(x, ((W)_x)_0, ((W)_x)_1)$. Hence $M_2 \models \exists W\, \forall x\, \eta(x, (W)_x)$. Thus $M_2$ is a model of $\Sigma^1_{k+2}$ choice. This completes the proof of lemma IX.4.8. □

The following theorem stands in contrast to results of §VII.7 according to which the minimum $\beta$-model of $\Delta^1_2$-CA$_0$ is much larger than that of $\Pi^1_1$-CA$_0$.

THEOREM IX.4.9 (conservation theorem). $\Sigma^1_2$-AC$_0$ (*hence also* $\Delta^1_2$-CA$_0$) *is conservative over* $\Pi^1_1$-CA$_0$ *for* $\Pi^1_3$ *sentences.*

PROOF. Let $\psi$ be a $\Pi^1_3$ sentence which is not provable in $\Pi^1_1$-CA$_0$. By Gödel's completeness theorem, let $M'$ be a model of $\Pi^1_1$-CA$_0$ in which $\psi$ is false. Writing $\psi \equiv \forall X\, \varphi(X)$ where $\varphi(X)$ is $\Sigma^1_2$, choose $A' \in \mathcal{S}_{M'}$ such that $M' \models \neg\varphi(A')$. By theorem VII.2.10, we can find a sequence of sets $A'_n \in \mathcal{S}_{M'}$, $n \in \omega$, such that $A' = A'_0$ and, for all $n$, $M' \models A'_{n+1}$ encodes a countable $\beta$-model of ACA$_0$ which contains $A'_n$. Thus the first order part of $M$ together with the sets $A'_n$, $n \in \omega$, form an $L_1(\underline{A})$-model of the axioms mentioned in lemma IX.4.8 (with $k = 0$) plus additional axioms saying "the countable $\omega$-model coded by $\underline{A}_{n+1}$ satisfies $\neg\varphi(\underline{A}_0)$." Hence, by lemma IX.4.2, there exists a recursively saturated model $M$ of these axioms. By lemma IX.4.8 (with $k = 0$), the associated $L_2$-structure $M_2$ satisfies $\Sigma^1_2$-AC$_0$. It is also clear that $M_2$ satisfies $\neg\varphi(\underline{A}_0)$, hence $M_2$ satisfies $\neg\psi$. Therefore, by the soundness theorem, $\psi$ is not provable in $\Sigma^1_2$-AC$_0$. It follows by theorem VII.6.9.1 that $\psi$ is not provable in $\Delta^1_2$-CA$_0$. This completes the proof of theorem IX.4.9. □

THEOREM IX.4.10 (consistency of $\Sigma^1_2$-AC$_0$).

1. $\Pi^1_1$-CA$_0$ *plus* $\Sigma^1_2$-IND *proves* $\Pi^1_3$ *correctness of* $\Sigma^1_2$-AC$_0$.
2. $\Sigma^1_2$-AC$_0$ *plus* $\Sigma^1_2$-IND *proves* $\Pi^1_4$ *correctness of* $\Sigma^1_2$-AC$_0$.
3. $\Pi^1_1$-CA$_0$ *plus* $\Sigma^1_2$-IND *proves the consistency of* $\Sigma^1_2$-AC$_0$.
4. $\Sigma^1_2$-AC$_0$ *does not prove* $\Sigma^1_2$-IND.

(Compare theorem VII.6.9.)

PROOF. These results are obtained by imitating the proofs of theorem IX.4.5 and corollaries IX.4.6 and IX.4.7 above, using lemma IX.4.8 instead of lemma IX.4.3. □

THEOREM IX.4.11 (conservation theorem). *For all $k < \omega$, $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ plus strong $\Sigma^1_{k+2}$-$\mathsf{DC}_0$ is conservative over strong $\Sigma^1_{k+2}$-$\mathsf{DC}_0$ for $\Pi^1_{k+4}$ sentences.*

PROOF. This result is obtained by imitating the proof of theorem IX.4.9, using theorem VII.7.4 (characterizing strong $\Sigma^1_{k+2}$-$\mathsf{DC}_0$ in terms of countable coded $\beta_{k+2}$-models) instead of theorem VII.2.10 (characterizing $\Pi^1_1$-$\mathsf{CA}_0$ in terms of countable coded $\beta$-models). □

The following corollary stands in contrast to results of §VII.7 according to which the minimum $\beta$-model of $\Delta^1_{k+3}$-$\mathsf{CA}_0$ is much larger than that of $\Pi^1_{k+2}$-$\mathsf{CA}_0$.

COROLLARY IX.4.12 (conservation theorem). *For all $k < \omega$, $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ (hence also $\Delta^1_{k+3}$-$\mathsf{CA}_0$) is conservative over $\Pi^1_{k+2}$-$\mathsf{CA}_0$ for $\Pi^1_4$ sentences.*

PROOF. This is immediate from theorem IX.4.11 plus the fact that strong $\Sigma^1_{k+2}$-$\mathsf{DC}_0$ is conservative over $\Pi^1_{k+2}$-$\mathsf{CA}_0$ for $\Pi^1_4$ sentences (theorems VII.6.9 and VII.6.20), recalling also that $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ includes $\Delta^1_{k+3}$-$\mathsf{CA}_0$ (lemma VII.6.6). □

EXERCISE IX.4.13 (conservation theorem). Show that, for all $k < \omega$, $\Sigma^1_{k+2}$-$\mathsf{AC}_0$ is conservative over $\Pi^1_{k+1}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+1}$-$\mathsf{AC}_0$ for $\Pi^1_{k+3}$ sentences.

THEOREM IX.4.14 (consistency of $\Sigma^1_{k+4}$-$\mathsf{AC}_0$). *Let $k < \omega$ be fixed.*

1. *Strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{IND}$ proves $\Pi^1_{k+4}$ correctness of strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{AC}_0$.*
2. *Strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{AC}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{IND}$ proves $\Pi^1_{k+5}$ correctness of strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{AC}_0$.*
3. *$\Pi^1_{k+3}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{IND}$ proves $\Pi^1_4$ correctness of strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{AC}_0$.*
4. *$\Pi^1_{k+3}$-$\mathsf{CA}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{IND}$ proves consistency of strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{AC}_0$.*
5. *$\Sigma^1_{k+4}$-$\mathsf{IND}$ is not provable from strong $\Sigma^1_{k+3}$-$\mathsf{DC}_0$ plus $\Sigma^1_{k+4}$-$\mathsf{AC}_0$.*

(Compare theorem VII.6.20.)

PROOF. Same as for theorem IX.4.10. □

**Notes for §IX.4.** For general background on saturated models, see Chang/Keisler [35] and Sacks [210]. Theorems IX.4.4 and IX.4.9 and corollary IX.4.12 are closely related to the conservation results of Friedman [64], with the difference that Friedman was considering systems with full induction. The concept of recursive saturation, as well as lemma IX.4.3 and theorem IX.4.4, are due to Barwise/Schlipf [15]. The fact that the existence of recursively saturated models is provable in $\mathsf{WKL}_0$ (lemma IX.4.2) appears to be new. Theorem IX.4.5 appears to be new. Corollaries IX.4.6 and IX.4.7 are due to Simpson [235]. Theorem IX.4.9 and

corollary IX.4.12 are due to Feferman and Feferman/Sieg respectively; see [29, §II.2]. The result of exercise IX.4.13 has been announced by Sieg and is proved in Schmerl [213, theorem 2.10]. Theorems IX.4.10, IX.4.11 and IX.4.14 appear to be new.

## IX.5. Gentzen-Style Proof Theory

In this section we briefly indicate the relationship between the material in this book and Gentzen-style proof theory. We state a few results and provide references to the published literature.

DEFINITION IX.5.1 (provable ordinals). Let $T_0$ be a subsystem of $\mathsf{Z}_2$ which includes $\mathsf{RCA}_0$. A *provable ordinal* of $T_0$ is a countable ordinal $\alpha$ such that, for some primitive recursive well ordering $W \subseteq \mathbb{N}$, $|W| = \alpha$ and $T_0$ proves $\mathrm{WO}(W)$. The supremum of the provable ordinals of $T_0$ is denoted $\mathrm{ord}(T_0)$. Note that if $T_0$ is any reasonable subsystem of $\mathsf{Z}_2$ then $\mathrm{ord}(T_0)$ is a recursive ordinal, i.e., $\mathrm{ord}(T_0) < \omega_1^{\mathrm{CK}}$.

REMARK IX.5.2. A principal focus of Gentzen-style proof theory is the computation of $\mathrm{ord}(T_0)$ for various well known subsystems $T_0$ of second order arithmetic. One of the tools used in such computations is cut elimination. Generally speaking, as $T_0$ gets stronger, $\mathrm{ord}(T_0)$ gets much larger and much more difficult to describe. It is interesting to note that these ordinals are closely related to consistency strength. Usually, if $\mathrm{ord}(T_0) = \mathrm{ord}(T_0')$ then $T_0$ and $T_0'$ are equiconsistent, and if $\mathrm{ord}(T_0) > \mathrm{ord}(T_0')$ then $T_0$ proves the consistency of $T_0'$.

Clearly non-$\omega$-models are relevant here. To see this, note that if $\alpha = \mathrm{ord}(T_0)$ then $T_0 + \neg\mathrm{WO}(\alpha)$ is consistent but any model of it is necessarily a non-$\omega$-model.

DEFINITION IX.5.3 (ordinal arithmetic). The operations of ordinal arithmetic are defined as usual by transfinite induction:

$$\begin{array}{lr} \text{addition:} & \alpha + \beta = \sup\{\alpha, (\alpha + \gamma) + 1 \colon \gamma < \beta\} \\ \text{multiplication:} & \alpha \cdot \beta = \sup\{\alpha \cdot \gamma + \alpha \colon \gamma < \beta\} \\ \text{exponentiation:} & \alpha^\beta = \sup\{1, \alpha^\gamma \cdot \alpha \colon \gamma < \beta\} \end{array}$$

Recall also that $\omega$ is the smallest infinite ordinal.

THEOREM IX.5.4 (provable ordinals of $\mathsf{RCA}_0$ and $\mathsf{WKL}_0$). *We have*

$$\mathrm{ord}(\mathsf{RCA}_0) = \mathrm{ord}(\mathsf{WKL}_0) = \omega^\omega.$$

PROOF. It is straightforward to show that, for each $n < \omega$, $\mathsf{RCA}_0$ proves $\mathrm{WO}(\omega^n)$. On the other hand, if $\mathrm{WO}(\omega^\omega)$ were provable in $\mathsf{WKL}_0$, then this would allow us to prove the totality of the Ackermann function, contradicting theorem IX.3.16 which says that $\mathsf{WKL}_0$ is conservative over primitive recursive arithmetic for $\Pi^0_2$ sentences. □

DEFINITION IX.5.5. Let $F$ be a function from ordinals to ordinals. $F$ is said to be *monotone* (respectively *strictly monotone*) if $\alpha < \beta$ implies $F(\alpha) \leq F(\beta)$ (respectively $F(\alpha) < F(\beta)$), and *continuous* if $F(\beta) = \sup\{F(\alpha)\colon \alpha < \beta\}$ for all limit ordinals $\beta$. A *fixed point* of $F$ is an ordinal $\alpha$ such that $F(\alpha) = \alpha$.

For each $\alpha > 1$ the functions $\beta \mapsto \alpha + \beta$, $\beta \mapsto \alpha \cdot \beta$, $\beta \mapsto \alpha^\beta$ are strictly monotone and continuous. It is well known that if $F$ is strictly monotone and continuous then $F$ has arbitrarily large fixed points. More generally, if $\{F_i\colon i \in I\}$ is any family of strictly monotone continuous functions, then there exist arbitrarily large *simultaneous fixed points* of $\{F_i\colon i \in I\}$, i.e., ordinals $\alpha$ such that $F_i(\alpha) = \alpha$ for all $i \in I$.

DEFINITION IX.5.6 (the ordinals $\varepsilon_0$ and $\Gamma_0$). For each ordinal $\alpha$ we define a strictly monotone continuous function $\varphi_\alpha$ from ordinals to ordinals as follows: $\varphi_0(\beta) = \omega^\beta$ and, for $\alpha > 0$, $\varphi_\alpha(\beta) =$ the $\beta$th simultaneous fixed point of the functions $\varphi_\gamma$, $\gamma < \alpha$. We put

$$\varepsilon_0 = \varphi_1(0) = \sup\left(\omega, \omega^\omega, \omega^{\omega^\omega}, \dots\right)$$

and more generally $\varepsilon_\alpha = \varphi_1(\alpha)$. $\Gamma_0$ is defined to be the least ordinal $\gamma > 0$ such that $\varphi_\alpha(\beta) < \gamma$ for all $\alpha, \beta < \gamma$. Note that

$$\omega < \omega^\omega < \omega^{\omega^\omega} < \cdots < \varepsilon_0 < \varepsilon_{\varepsilon_0} < \cdots < \varphi_2(0) < \varphi_2(1) < \cdots < \Gamma_0.$$

It can be shown that $\varepsilon_0$ and $\Gamma_0$ are recursive ordinals.

THEOREM IX.5.7 (provable ordinals of $\mathsf{ACA}_0$ and $\mathsf{ATR}_0$). *We have*

$$\mathrm{ord}(\mathsf{ACA}_0) = \varepsilon_0$$

*and*

$$\mathrm{ord}(\mathsf{ATR}_0) = \Gamma_0.$$

PROOF. We have seen in §VIII.1 that the first order part of $\mathsf{ACA}_0$ is Peano arithmetic, PA, i.e., first-order arithmetic, $\mathsf{Z}_1$. The proof-theoretic analysis of $\mathsf{Z}_1$ in terms of $\varepsilon_0$ goes back to Gentzen; see for instance Takeuti [261] and Schütte [214]. The fact that $\mathrm{ord}(\mathsf{ATR}_0) = \Gamma_0$ is due to Friedman/McAloon/Simpson [76]. Earlier Feferman [56, 57] had introduced his system IR of predicative analysis and showed that $\mathrm{ord}(\mathsf{IR}) = \Gamma_0$. See also remark I.11.9. □

DEFINITION IX.5.8 (collapsing functions). We write $\Omega_0 = 0$ and $\Omega_n = \aleph_n =$ the $n$th infinite initial ordinal, for $1 \leq n < \omega$. Following Buchholz/Schütte [30] we define *collapsing functions* $\Psi_i(\alpha)$, $i < \omega$, by induction on $\alpha$. First let $C_i(\alpha)$ be the smallest set of ordinals such that

1. $\{\Omega_n\colon n < \omega\} \cup \{\xi\colon \xi < \Omega_i\} \subseteq C_i(\alpha)$;
2. if $\xi, \eta \in C_i(\alpha)$, then also $\xi + \eta, \omega^\xi \in C_i(\alpha)$;

3. if $\xi \in C_i(\alpha)$ and $\xi < \alpha$, then also $\Psi_j(\xi) \in C_i(\alpha)$ for all $j \geq i$, $j < \omega$.

Then $\Psi_i(\alpha)$ is defined to be the smallest $\beta$ such that $\beta \notin C_i(\alpha)$.

REMARK IX.5.9. Each $\Psi_i$, $i < \omega$, is monotone and continuous. In particular, we have $\Psi_0(\Omega_\omega) = \sup\{\Psi_0(\Omega_n) : n < \omega\}$. This turns out to be a recursive ordinal. It can also be characterized in terms of Takeuti's ordinal diagrams of finite order; see Takeuti [261, chapter 5].

THEOREM IX.5.10 (provable ordinals of $\Pi^1_1$-$\mathsf{CA}_0$). *We have*

$$\mathrm{ord}(\Pi^1_1\text{-}\mathsf{CA}_0) = \Psi_0(\Omega_\omega).$$

PROOF. This is an advanced result of Gentzen-style proof theory. See Takeuti [261], Schütte [214], Buchholz/Schütte [30], and Buchholz/Feferman/Pohlers/Sieg [29]. □

REMARK IX.5.11 (mathematical independence results). Gentzen-style proof theory has been used to obtain various independence results for subsystems of $\mathsf{Z}_2$. Friedman (see Simpson [239, 240]) used theorem IX.5.7 to show that Kruskal's theorem is not provable in $\mathsf{ATR}_0$; Friedman/Robertson/Seymour [77] used theorem IX.5.10 to show that the graph minor theorem is not provable in $\Pi^1_1$-$\mathsf{CA}_0$; see remark X.3.23 below. There are some closely related finite combinatorial independence results; Simpson [244] provides an overview of this area. Simpson [245] used theorem IX.5.4 to show that the Hilbert basis theorem is not provable in $\mathsf{RCA}_0$; see remark X.3.21 below.

## IX.6. Conclusions

In §§IX.1–IX.4 we have used non-$\omega$-models to obtain some striking conservation results. The simplest such result is that $\mathsf{ACA}_0$ is conservative over first order arithmetic, PA. In addition, $\mathsf{RCA}_0$ and $\mathsf{WKL}_0$ are conservative over $\Sigma^0_1$-PA, which is in turn conservative over primitive recursive arithmetic for $\Pi^0_2$ sentences. By remark IX.3.18, the latter result is of great significance with respect to Hilbert's program of finite reductionism. In addition, we obtained some surprising results concerning choice schemes: $\Sigma^1_1$-$\mathsf{AC}_0$ is conservative over $\mathsf{ACA}_0$ for $\Pi^1_2$ sentences; $\Sigma^1_2$-$\mathsf{AC}_0$ is conservative over $\Pi^1_1$-$\mathsf{CA}_0$ for $\Pi^1_3$ sentences; for each $k < \omega$, $\Sigma^1_{k+3}$-$\mathsf{AC}_0$ is conservative over $\Pi^1_{k+2}$-$\mathsf{CA}_0$ for $\Pi^1_4$ sentences. In §IX.5 we ended the chapter with some very brief remarks on Gentzen-style proof theory, specifically provable ordinals.

# APPENDIX

Chapter X

# ADDITIONAL RESULTS

This appendix is a supplement to chapters I through IX. We outline various results without proof but with references to the published literature.

## X.1. Measure Theory

In this section we discuss measure theory in the context of subsystems of second order arithmetic.

Measure theory is a particularly interesting topic from the viewpoint of the Main Question and Reverse Mathematics (chapter I). Recall from §§I.1 and I.12 that the Main Question concerns the role of set existence axioms. Historically, the subject of measure theory developed hand in hand with the nonconstructive, set-theoretic approach to mathematics. Bishop has remarked that the foundations of measure theory present a special challenge to the constructive mathematician. Although Reverse Mathematics is quite different from Bishop-style constructivism (see remarks I.8.9 and IV.2.8), we feel that Bishop's remark implicitly raises an interesting question: *Which nonconstructive set existence axioms are needed for measure theory*?

**Measure Theory in $\mathsf{RCA}_0$.** We begin by noting that some basic measure-theoretic notions can be defined in $\mathsf{RCA}_0$.

Definition X.1.1 (Borel measures). Within $\mathsf{RCA}_0$, let $X$ be a compact metric space. Recall from exercise IV.2.13 the separable Banach space $\mathrm{C}(X)$. A *Borel measure on* $X$ (more accurately, a nonnegative Borel probability measure on $X$) is defined to be a nonnegative bounded linear functional $\mu\colon \mathrm{C}(X) \to \mathbb{R}$ such that $\mu(1) = 1$. See also definition IV.2.14.

Definition X.1.2 (measure of an open set). Within $\mathsf{RCA}_0$, let $X$ be a compact metric space, and let $\mu$ be a Borel measure on $X$. If $U$ is an open set in $X$, we define

$$\mu(U) = \sup\{\mu(\phi) \mid \phi \in \mathrm{C}(X), 0 \leq \phi \leq 1, \phi = 0 \text{ on } X \setminus U\}.$$

Note that, within $\mathsf{RCA}_0$, the above supremum need not exist as a real number. Indeed, the existence of $\mu(U)$ for all open sets $U$ is equivalent

to $\mathsf{ACA}_0$ over $\mathsf{RCA}_0$. See also Yu [277], where it is shown that a certain version of the Riesz representation theorem is equivalent over $\mathsf{RCA}_0$ to arithmetical comprehension.

Therefore, when working in $\mathsf{RCA}_0$ in situations when arithmetical comprehension is not available, we interpret statements about $\mu(U)$ in a "virtual" or comparative sense. For example, $\mu(U) \leq \mu(V)$ is taken to mean that for all $\epsilon > 0$ and all $\phi \in \mathrm{C}(X)$ with $0 \leq \phi \leq 1$ and $\phi = 0$ on $X \setminus U$, there exists $\psi \in \mathrm{C}(X)$ with $0 \leq \psi \leq 1$ and $\psi = 0$ on $X \setminus V$ such that $\mu(\phi) \leq \mu(\psi) + \epsilon$.

EXAMPLES X.1.3. *Lebesgue measure* measure on the closed unit interval $[0,1]$ is given by the bounded linear functional $\mu\colon \mathrm{C}[0,1] \to \mathbb{R}$ where $\mu(\phi) = \int_0^1 \phi(x)\,dx$, the Riemann integral of $\phi$ from 0 to 1. It can be shown that the Lebesgue measure of an open interval is the length of the interval. There is also the obvious generalization to Lebesgue measure on the $n$-cube $[0,1]^n$. Another example is the familiar *fair coin measure* on the Cantor space $2^{\mathbb{N}}$, given by $\mu(\{x \mid x(n) = i\}) = 1/2$ for all $n \in \mathbb{N}$ and $i \in \{0,1\}$.

DEFINITION X.1.4 (countable additivity, etc.). Within $\mathsf{RCA}_0$, let $X$ be a compact metric space and let $\mu$ be a Borel measure on $X$. We say that $\mu$ is *countably additive* if

$$\mu\left(\bigcup_{n=0}^{\infty} U_n\right) = \lim_{k\to\infty} \mu\left(\bigcup_{n=0}^{k} U_n\right)$$

for any sequence of open sets $U_n \subseteq X$, $n \in \mathbb{N}$; *disjointly countably additive* if

$$\mu\left(\bigcup_{n=0}^{\infty} U_n\right) = \sum_{n=0}^{\infty} \mu(U_n)$$

for any sequence of pairwise disjoint open sets $U_n \subseteq X$, $n \in \mathbb{N}$; *finitely additive* if

$$\mu(U) + \mu(V) = \mu(U \cup V) + \mu(U \cap V)$$

for all open $U, V \subseteq X$.

DEFINITION X.1.5 (nice metric spaces). An open set is said to be *connected* if it is not the union of two disjoint nonempty open sets. A separable metric space $X$ is said to be *nice* if for all sufficiently small $\delta > 0$ and all $x \in X$, the open ball

$$\mathrm{B}(x,\delta) = \{y \in X \mid d(x,y) < \delta\}$$

is connected. Such a $\delta$ is called a *modulus of niceness* for $X$.

For example, the unit interval $[0,1]$ and the $n$-cube $[0,1]^n$ are nice, but the Cantor space $2^{\mathbb{N}}$ is not nice.

Theorem X.1.6 (disjoint countable additivity). *The following is provable in* $\mathsf{RCA}_0$. *Let $X$ be a compact metric space, and let $\mu$ be a Borel measure on $X$. If $X$ is nice, then $\mu$ is disjointly countably additive.*

Proof. See Brown/Giusto/Simpson [26]. □

**Measure Theory in** $\mathsf{WWKL}_0$**.** In order to obtain countable additivity, we need an axiom which goes beyond $\mathsf{RCA}_0$ yet is weaker than weak König's lemma.

Definition X.1.7 (weak weak König's lemma). We define *weak weak König's lemma* to be the following axiom: if $T$ is a subtree of $2^{<\mathbb{N}}$ with no infinite path, then

$$\lim_{n\to\infty} \frac{|\{\sigma \in T \mid \mathrm{lh}(\sigma) = n\}|}{2^n} = 0.$$

Note that weak weak König's lemma is a consequence of weak König's lemma, which reads as follows: if $T$ is a subtree of $2^{<\mathbb{N}}$ with no infinite path, then $T$ is finite.

$\mathsf{WWKL}_0$ is the subsystem of $\mathsf{Z}_2$ consisting of $\mathsf{RCA}_0$ plus weak weak König's lemma.

Remark X.1.8 ($\omega$-models of $\mathsf{WWKL}_0$). It is known that

$$\mathsf{RCA}_0 \quad \subsetneq \quad \mathsf{WWKL}_0 \quad \subsetneq \quad \mathsf{WKL}_0$$

and there are $\omega$-models for the independence. For the first inequality, note that the $\omega$-model REC consisting of the recursive subsets of $\omega$ (see remark I.7.5) does not satisfy $\mathsf{WWKL}_0$. For the second inequality, one can easily construct an $\omega$-model of $\mathsf{WWKL}_0$, namely a random real model, which does not satisfy $\mathsf{WKL}_0$. See for example Yu/Simpson [280]. The study of $\omega$-models of $\mathsf{WWKL}_0$ is closely related to the theory of 1-random sequences, as initiated by Martin-Löf [179] and continued by Kučera [156, 157, 158].

Theorem X.1.9 (countable additivity). *The following assertions are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Weak weak König's lemma.*
2. *For any compact metric space $X$ and any Borel measure $\mu$ on $X$, $\mu$ is countably additive.*
3. *For any covering of the closed unit interval* $[0, 1]$ *by a sequence of open intervals $(a_n, b_n)$, $n \in \mathbb{N}$, we have $\sum_{n=0}^{\infty} |a_n - b_n| \geq 1$.*

Proof. See Yu/Simpson [280], Brown/Giusto/Simpson [26], and Simpson [248]. □

Theorem X.1.10 (finite additivity). *The following statements are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Weak weak König's lemma.*
2. *Any Borel measure $\mu$ on a compact metric space is finitely additive.*

3. *If $\mu$ is the fair coin measure on the Cantor space $X = 2^{\mathbb{N}}$, then for any two open sets $U, V \subseteq X$ with $X = U \cup V$ and $U \cap V = \emptyset$ we have $\mu(U) + \mu(V) = 1$.*

PROOF. See Simpson [248]. □

It turns out that $\mathsf{WWKL}_0$ is sufficient to develop a fair amount of measure theory and to prove several key theorems, as we now show.

REMARK X.1.11 (measurable functions). Let $X$ be a compact metric space and let $\mu$ be a Borel measure on $X$. Recall from exercise IV.2.15 that there is a separable Banach space $\mathrm{L}_1(X, \mu)$ with the $\mathrm{L}_1$-norm given by $\|f\|_1 = \mu(|f|)$. For $f \in \mathrm{L}_1(X, \mu)$ we define $\int f \, d\mu = \mu(f)$. All of this makes sense in $\mathsf{RCA}_0$.

An obvious question is whether elements of the separable Banach space $\mathrm{L}_1(X, \mu)$ can be identified with real-valued measurable functions on $X$ in the usual way. The answer is that this can be done in $\mathsf{WWKL}_0$. Namely, given $f \in \mathrm{L}_1(X, \mu)$, we know in $\mathsf{RCA}_0$ that $f$ is given by a sequence of real-valued continuous functions $\phi_n \in \mathrm{C}(X)$, $n \in \mathbb{N}$, which converges in the $\mathrm{L}_1$-norm, indeed $\|\phi_m - \phi_{m'}\|_1 \leq 1/2^n$ for all $m, m', n \in \mathbb{N}$ with $m, m' \geq n$. We can prove in $\mathsf{WWKL}_0$ that this sequence converges pointwise almost everywhere, in the following sense: There is a sequence of closed sets

$$C_0^f \subseteq C_1^f \subseteq \cdots \subseteq C_n^f \subseteq \cdots, \ n \in \mathbb{N}$$

such that $\mu(X \setminus C_n^f) \leq 1/2^n$ for all $n$, and $|\phi_m(x) - \phi_{m'}(x)| \leq 1/2^k$ for all $x \in C_n^f$ and all $m$, $m'$, $k$ such that $m, m' \geq n + 2k + 2$. We then define $f(x) = \lim_{n\to\infty} \phi_n(x)$ for all $x \in \bigcup_{n=0}^{\infty} C_n^f$. Thus we see that $f(x)$ is defined for almost all $x \in X$. Moreover, $f = g$ in $\mathrm{L}_1(X, \mu)$, i.e., if $\|f - g\|_1 = 0$, if and only if $f(x) = g(x)$ for almost all $x \in X$. These facts are provable in $\mathsf{WWKL}_0$.

The above remarks on pointwise values of measurable functions are due to Yu [275, 278].

Our approach to measurable sets within $\mathsf{WWKL}_0$ is to identify them with their characteristic functions in $\mathrm{L}_1(X, \mu)$, according to the following definition.

DEFINITION X.1.12 (measurable sets). We say that $f \in \mathrm{L}_1(X, \mu)$ is a *measurable characteristic function* if $f(x) \in \{0, 1\}$ for almost all $x \in X$, i.e., there exists a sequence of closed sets

$$C_0 \subseteq C_1 \subseteq \cdots \subseteq C_n \subseteq \ldots, \quad n \in \mathbb{N},$$

such that $\mu(X \setminus C_n) \leq 1/2^n$ for all $n$, and $f(x) \in \{0, 1\}$ for all $x \in \bigcup_{n=0}^{\infty} C_n$. Here $f(x)$ is as defined in remark X.1.11. A (code for a) *measurable set* $E$ with respect to $(X, \mu)$ is defined to be a measurable characteristic function $f \in \mathrm{L}_1(X, \mu)$. We then define $\mu(E) = \mu(f)$, and the complementary set $X \setminus E$ is defined as $1 - f$. If $E_1$ and $E_2$

are measurable sets with measurable characteristic functions $f_1$ and $f_2$, then $E_1 \cup E_2$ and $E_1 \cap E_2$ are defined as $\sup(f_1, f_2)$, $\inf(f_1, f_2)$ respectively. Other set operations on measurable sets are defined similarly.

For more on measurable sets in the context of subsystems of $\mathsf{Z}_2$, see Brown/Giusto/Simpson [26] and Giusto's thesis [91].

With the above notion of measurable set, we can show that $\mathsf{WWKL}_0$ is just strong enough to prove a version of the Vitali covering theorem. We consider only Lebesgue measure $\mu$ on $[0, 1]$. Let $\mathcal{I}$ be a sequence of intervals in $[0, 1]$. We say that $\mathcal{I}$ *Vitali covers* an interval $E \subseteq [0, 1]$ if for all $x \in E$ and all $\epsilon > 0$ there exists $I \in \mathcal{I}$ such that $x \in I$ and $\text{length}(I) < \epsilon$. We say that $\mathcal{I}$ *almost Vitali covers* a Lebesgue measurable set $E \subseteq [0, 1]$ if for all $\epsilon > 0$ we have $\mu(E \setminus O_\epsilon) = 0$, where $O_\epsilon = \bigcup\{I : I \in \mathcal{I}, \text{length}(I) < \epsilon\}$.

THEOREM X.1.13 (Vitali covering theorem). *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Weak weak König's lemma.*
2. *If $\mathcal{I}$ Vitali covers an interval $E$, then $\mathcal{I}$ contains a pairwise disjoint sequence of intervals $I_n$, $n \in \mathbb{N}$, such that $\mu(E \setminus \bigcup_{n=0}^{\infty} I_n) = 0$.*
3. *If $\mathcal{I}$ almost Vitali covers a Lebesgue measurable set $E$, then $\mathcal{I}$ contains a pairwise disjoint sequence of intervals $I_n$, $n \in \mathbb{N}$, such that $\mu(E \setminus \bigcup_{n=0}^{\infty} I_n) = 0$.*

PROOF. See Brown/Giusto/Simpson [26]. □

We now discuss the Lebesgue convergence theorems. Let $\mu$ be a Borel measure on a compact metric space $X$. The *monotone convergence theorem* for $\mu$ asserts that if $f, f_n \in \mathrm{L}_1(X, \mu)$, $n \in \mathbb{N}$, and if $\langle f_n(x) : n \in \mathbb{N} \rangle$ is increasing and converges to $f(x)$ for almost all $x \in X$, then $\lim_n \|f_n - f\|_1 = 0$ and $\lim_n \int f_n \, d\mu = \int f \, d\mu$.

THEOREM X.1.14 (monotone convergence theorem). *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. *Weak weak König's lemma.*
2. *The monotone convergence theorem for Borel measures on compact metric spaces.*
3. *The monotone convergence theorem for Lebesgue measure on* $[0, 1]$.

PROOF. See Yu [278]. □

REMARK X.1.15 (dominated convergence theorem). We conjecture that the *dominated convergence theorem* is also equivalent to weak weak König's lemma over $\mathsf{RCA}_0$. This is the assertion that if $f, g, f_n \in \mathrm{L}_1(X, \mu)$, $n \in \mathbb{N}$, and if $|f_n(x)| \leq g(x)$ for all $n \in \mathbb{N}$ and $\lim_n f_n(x) = f(x)$ for almost all $x \in X$, then $\lim_n \|f_n - f\|_1 = 0$ and $\lim_n \int f_n \, d\mu = \int f \, d\mu$. For the background of this conjecture, see Yu [278].

**Measure Theory in $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$.** We end this section by noting that some set existence axioms going beyond $\mathsf{WWKL}_0$ are sometimes useful in measure theory.

Remark X.1.16 (Haar measure in $\mathsf{WKL}_0$). Let $G$ be a *separable compact group*, i.e., a compact separable metric space with continuous group operations. *Haar measure* on $G$ is the unique invariant Borel measure on $G$. It is known that the existence of Haar measure for separable compact groups is equivalent over $\mathsf{RCA}_0$ to weak König's lemma; this result is due to Tanaka/Yamazaki [265].

Remark X.1.17 (measure theory in $\mathsf{ACA}_0$). Clearly $\mathsf{ACA}_0$ is useful in measure theory. For example, $\mathsf{ACA}_0$ implies that the class of measurable sets (definition X.1.12) is closed under countable unions and intersections. Moreover, Yu [276, 277, 279] has shown that $\mathsf{ACA}_0$ is equivalent over $\mathsf{RCA}_0$ to several specific measure-theoretic theorems: (1) a certain form of the Radon/Nikodym theorem for Borel measures on compact metric spaces; (2) a certain form of the Riesz representation theorem for Borel measures on compact metric spaces; (3) enumerability of the set of singular points of an arbitrary Borel measure on the Cantor space.

Remark X.1.18 (measure theory in $\mathsf{ATR}_0$). Yu [277] has noted that $\mathsf{ATR}_0$ suffices to prove measurability and regularity of Borel sets with respect to any Borel measure on a compact metric space. It is unclear whether $\mathsf{ATR}_0$ suffices to prove measurability and regularity of analytic sets in some appropriate sense.

Remark X.1.19. Additional results on analysis in $\mathsf{RCA}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$ and related systems are in Brown [24, 25], Giusto/Marcone [92], Giusto/Simpson [93], Hardin/Velleman [101].

**Notes for §X.1.** The material in this section is from Yu [275, 276, 277, 278, 279], Yu/Simpson [280], Brown/Giusto/Simpson [26], Giusto [91], Tanaka/Yamazaki [265], and Simpson [248].

## X.2. Separable Banach Spaces

In this section we present some results on the theory of separable Banach spaces in subsystems of $\mathsf{Z}_2$. This builds on the material that has already been presented in §§II.10 and IV.9.

**Banach Separation.** We begin with the so-called geometric form of the Hahn/Banach theorem. Let $X$ be a separable Banach space. As in §IV.9, a *bounded linear functional* on $X$ is a bounded linear operator $f : X \to \mathbb{R}$. Let $A$ and $B$ be convex sets in $X$. We say that $A$ and $B$ are *separated* if

there exists a bounded linear functional $f : X \to \mathbb{R}$ and a real number $\alpha$ such that $f(x) < \alpha$ for all $x \in A$, and $f(x) \geq \alpha$ for all $x \in B$. We say that $A$ and $B$ are *strictly separated* if in addition $f(x) > \alpha$ for all $x \in B$.

Theorem X.2.1 (Banach separation in $\mathsf{WKL}_0$). $\mathsf{WKL}_0$ *is equivalent over* $\mathsf{RCA}_0$ *to the following statement. If $A$ and $B$ are open convex sets in a separable Banach space $X$, and if $A \cap B = \emptyset$, then $A$ and $B$ can be strictly separated.*

Proof. This and related results are due to Humphreys/Simpson [128]. The proof of Banach separation in $\mathsf{WKL}_0$ is accomplished by means of a reduction to the case of finite-dimensional Banach spaces, using a compactness argument. The reversal is obtained via the Brown/Simpson [27] reversal of the Hahn/Banach theorem; see also theorem IV.9.4. □

Remark X.2.2. Hatzikiriakou [111] has shown that $\mathsf{WKL}_0$ is also equivalent over $\mathsf{RCA}_0$ to an algebraic separation theorem for countable vector spaces over $\mathbb{Q}$. We do not see any easy way to deduce Hatzikiriakou's result from theorem X.2.1 or vice versa, but the comparison is interesting.

**Dual Spaces and Alaoglu's Theorem.** Next we consider dual spaces and the Banach/Alaoglu theorem. Let $X$ be a separable Banach space. The following definitions are made in $\mathsf{RCA}_0$.

Definition X.2.3 (dual space, Alaoglu ball). We write $f \in X^*$ to mean that $f$ is a bounded linear functional on $X$. Thus $X^*$ is the *dual space* of $X$. For $0 < r < \infty$, we write $f \in \mathrm{B}_r(X^*)$ to mean that $f \in X^*$ and $\|f\| \leq r$. Note that $X^*$ and $\mathrm{B}_r(X^*)$ do not formally exist as sets within $\mathsf{RCA}_0$. We identify the functionals in $\mathrm{B}_r(X^*)$ in the obvious way with the points of a certain closed set in the compact metric space $\prod_{a \in A}[-r\|a\|, r\|a\|]$, where $X = \widehat{A}$.

Remark X.2.4 (Banach/Alaoglu theorem in $\mathsf{WKL}_0$). Using definition X.2.3 and lemmas III.2.5 and IV.1.5, we see that Heine/Borel compactness of $\mathrm{B}_r(X^*)$ is provable in $\mathsf{WKL}_0$. This version of the Banach/Alaoglu theorem is very useful for the development of separable Banach space theory within $\mathsf{WKL}_0$. See also Brown's [24] discussion of the Alaoglu ball.

**The Weak-$*$ Topology.** Finally we consider the weak-$*$ topology. As before, let $X$ be a separable Banach space. We shall observe that $\Pi^1_1$ comprehension is needed to prove some basic results about weak-$*$ closed subspaces of $X^*$.

Definition X.2.5 (bounded-weak-$*$ topology). A (code for a) *bounded-weak-$*$-closed set* $C$ in $X^*$ is defined to be a sequence of (codes for) closed sets $C_n \subseteq \mathrm{B}_n(X^*)$, $n \in \mathbb{N}$, such that

$$\forall m \, \forall n \, (m < n \to C_m = \mathrm{B}_m(X^*) \cap C_n).$$

We write $x^* \in C$ to mean $\exists n\,(x^* \in C_n)$, or equivalently $\forall n\,(n > \|x^*\| \to x^* \in C_n)$. A *bounded-weak-$*$-open set* in $X^*$ is defined to be the complement of a bounded-weak-$*$-closed set in $X^*$.

DEFINITION X.2.6 (weak-$*$ topology). A *weak-$*$-open set* in $X^*$ is defined to be a bounded-weak-$*$-open set $U$ in $X^*$ such that for all $x_0^* \in U$ there exists a finite sequence of points $x_0, \dots, x_{n-1} \in X$ such that

$$\{x^* \in X^* \colon \forall k < n\,(|x^*(x_k) - x_0^*(x_k)| \le 1)\} \subseteq U.$$

A *weak-$*$-closed set* in $X^*$ is defined to be the complement of a weak-$*$-open set in $X^*$.

Clearly there is a weak-$*$ neighborhood basis of 0 in $X^*$ consisting of the polars of finite sets in $X$. Humphreys/Simpson [127, lemma 4.12] have shown that the following well known fact is provable in $\mathsf{ACA}_0$: There is a bounded-weak-$*$ neighborhood basis of 0 in $X^*$ consisting of the polars of sequences converging to 0 in $X$. We do not know whether $\mathsf{WKL}_0$ suffices.

THEOREM X.2.7 (Krein/Šmulian theorem in $\mathsf{ACA}_0$). *The following is provable in $\mathsf{ACA}_0$. Let $X$ be a separable Banach space. Suppose that $C \subseteq X^*$ is convex and bounded-weak-$*$-closed. Then $C$ is weak-$*$-closed.*

PROOF. This is theorem 4.14 of Humphreys/Simpson [127]. Again, we do not know whether $\mathsf{WKL}_0$ suffices. □

Specializing to subspaces of $X^*$ we obtain:

COROLLARY X.2.8. *The following is provable in $\mathsf{ACA}_0$. Let $X$ be a separable Banach space. Let $C$ be a closed set in $\mathrm{B}_1(X^*)$ such that $C = \mathrm{B}_1(X^*) \cap \mathrm{span}(C)$. Then $\mathrm{span}(C)$ is a weak-$*$-closed subspace of $X^*$.*

(Here $\mathrm{span}(C)$ denotes the linear span of $C$.)

The following theorem is interesting because it shows that a rather strong set existence axiom, $\Pi^1_1$ comprehension, is needed to prove a rather trivial-sounding statement about the weak-$*$ topology: For every countable set $Y \subset X^*$, the weak-$*$-closed linear span of $Y$ exists.

Recall from example II.10.2 that $\ell_1$ is the separable Banach space of absolutely summable sequences of real numbers. It may be viewed as the dual of the space $c_0$ of sequences of real numbers which are convergent to 0, with the sup norm.

THEOREM X.2.9 (weak-$*$ topology and $\Pi^1_1$-$\mathsf{CA}_0$). *The following are pairwise equivalent over $\mathsf{RCA}_0$.*

1. $\Pi^1_1$-$\mathsf{CA}_0$.
2. *For every separable Banach space $X$ and countable set $Y \subseteq X^*$, there exists a smallest weak-$*$-closed set in $X^*$ containing $Y$.*
3. *For every separable Banach space $X$ and countable set $Y \subseteq X^*$, there exists a smallest weak-$*$-closed convex set in $X^*$ containing $Y$.*

4. *For every separable Banach space $X$ and countable set $Y \subseteq X^*$, there exists a smallest weak-$*$-closed subspace of $X^*$ containing $Y$.*
5. *Same as* 2 *with* $X = c_0$ *and* $X^* = \ell_1$.
6. *Same as* 3 *with* $X = c_0$ *and* $X^* = \ell_1$.
7. *Same as* 4 *with* $X = c_0$ *and* $X^* = \ell_1$.

PROOF. This is theorem 5.6 of Humphreys/Simpson [127]. The proof uses the notion of smooth tree (exercise VI.1.9) and is correlated to transfinite iteration of weak-$*$ sequential closure. For details, see [127]. □

**Notes for §X.2.** The results of this section are from Humphreys/Simpson [127, 128]. See also Humphreys [126]. For a study of the open mapping and closed graph theorems in subsystems of $\mathsf{Z}_2$, see Brown/Simpson [28] and Brown [24].

## X.3. Countable Combinatorics

In this section we present some results on countable combinatorics in subsystems of $\mathsf{Z}_2$.

**Hindman's Theorem and Dynamical Systems.** We have seen in §III.7 that Ramsey's theorem for exponent 3 is equivalent over $\mathsf{RCA}_0$ to $\mathsf{ACA}_0$. The purpose of this subsection is to consider the status of other Ramsey-type combinatorial theorems.

DEFINITION X.3.1 (Hindman's theorem). Given $X \subseteq \mathbb{N}$, let $\mathrm{FS}(X)$ be the set of all sums of finite nonempty subsets of $X$. *Hindman's theorem* says: If $\mathbb{N} = C_0 \cup \cdots \cup C_l$ then there exists an infinite set $X \subseteq \mathbb{N}$ such that $\mathrm{FS}(X) \subseteq C_i$ for some $i \leq l$.

There has been considerable interest in the issue of whether Hindman's theorem holds constructively; see [21] for some of the history. From the standpoint of Reverse Mathematics, we conjecture that Hindman's theorem is equivalent over $\mathsf{RCA}_0$ to $\mathsf{ACA}_0$. We now present some partial results in this direction.

DEFINITION X.3.2 (the system $\mathsf{ACA}_0^+$). Let $\mathsf{ACA}_0^+$ consist of $\mathsf{ACA}_0$ plus the assertion that for any $X \subseteq \mathbb{N}$ the $\omega$th Turing jump $\mathrm{TJ}(\omega, X)$ exists. Here $\omega$ denotes the order type of $\mathbb{N}$ under $\leq_{\mathbb{N}}$. Note that $\mathsf{ACA}_0^+$ is closely related to the predicative system of Weyl [274].

We have:

THEOREM X.3.3 (Hindman's theorem and $\mathsf{ACA}_0$).

1. *Hindman's theorem is provable in* $\mathsf{ACA}_0^+$.
2. *Hindman's theorem implies* $\mathsf{ACA}_0$ *over* $\mathsf{RCA}_0$.

PROOF. These results are from Blass/Hirst/Simpson [21]. □

The Auslander/Ellis theorem is a well known theorem of topological dynamics. It is closely related to Hindman's theorem; see Furstenberg [84] and Graham/Rothschild/Spencer [98]. Just as in the case of Hindman's theorem, we conjecture that the Auslander/Ellis theorem is equivalent over $\mathsf{RCA}_0$ to $\mathsf{ACA}_0$, and we present some partial results. First we review the relevant definitions.

Definitions X.3.4 (uniform recurrence, etc.). A *dynamical system* consists of a compact metric space $X$ and a continuous function $T\colon X \to X$. For $x \in X$ and $n \in \mathbb{N}$ we write

$$T^n(x) = \underbrace{TT\cdots T}_{n}(x).$$

A point $x \in X$ is called *recurrent* if for all $\epsilon > 0$ there exist infinitely many $n$ such that $d(T^n(x), x) < \epsilon$. We say that $x$ is *uniformly recurrent* if for all $\epsilon > 0$ there exists $m$ such that for all $n$ there exists $k < m$ such that $d(T^{n+k}(x), x) < \epsilon$. Two points $x, y \in X$ are said to be *proximal* if for all $\epsilon > 0$ there exist infinitely many $n$ such that $d(T^n(x), T^n(y)) < \epsilon$. The *Auslander/Ellis theorem* says: For all $x \in X$ there exists $y \in X$ such that $y$ is proximal to $x$ and uniformly recurrent.

Theorem X.3.5 (Auslander/Ellis theorem and $\mathsf{ACA}_0$).

1. *The Auslander/Ellis theorem is provable in* $\mathsf{ACA}_0^+$.
2. *The existence of uniformly recurrent points is provable in* $\mathsf{ACA}_0$.

Proof. These results are from Blass/Hirst/Simpson [21]. The proof of part 1 proceeds via Hindman's theorem and uses X.3.3.1. Part 2 may be compared with Girard [90, annex 7.E]. □

Remark X.3.6 (open problems). There are many other open problems concerning the Reverse Mathematics status of various theorems of countable combinatorics. Among these are Szemerédi's theorem (see Furstenberg [84] and Graham/Rothschild/Spencer [98]) and its generalizations due to Furstenberg/Katznelson [85, 86, 87]. There is also the Carlson/Simpson theorem [33, 34] (see also Blass/Hirst/Simpson [21] and Simpson [242]) and its generalizations due to Carlson [31, 32] (see also Hindman/Strauss [116]).

Remark X.3.7. Another contribution to Reverse Mathematics for dynamical systems is Friedman/Simpson/Yu [80].

**Matching Theory.** We now turn from Ramsey theory to another branch of combinatorics known as matching theory or transversal theory. General references on this subject are Jungnickel [135], Mirsky [190], and Holz/Podewski/Steffens [124].

Definition X.3.8 (matchings). A *bipartite graph* is an ordered triple $G = (X, Y, E)$ such that $X$ and $Y$ are sets, $X \cap Y = \emptyset$, and $E \subseteq$

$\{\{x, y\}: x \in X, y \in Y\}$. The *vertices* of $G$ are the elements of $X \cup Y$. The *edges* of $G$ are the elements of $E$. A *vertex covering* of $G$ is a set $C \subseteq X \cup Y$ such that every edge of $G$ has a vertex in $C$. A *matching* in $G$ is a pairwise disjoint set $M \subseteq E$. Here pairwise disjointness means that no two edges in $M$ have a common vertex.

REMARK X.3.9 (König duality theorem). For any set $S$ we use $|S|$ to denote the cardinality of $S$. If $G$ is any bipartite graph and $C$ is any vertex covering of $G$ and $M$ is any matching in $G$, then clearly $|C| \geq |M|$. The *König duality theorem* asserts that for any finite bipartite graph $G$ there exist a vertex covering $C$ of $G$ and a matching $M$ in $G$ such that $|C| = |M|$. In other words, $\min\{|C|: C \text{ is a vertex covering of } G\} = \max\{|M|: M \text{ is a matching in } G\}$.

DEFINITION X.3.10 (König coverings). For any bipartite graph $G$, a *König covering* of $G$ is an ordered pair $(C, M)$ such that $C$ is a vertex covering of $G$, $M$ is a matching in $G$, and $C$ consists of exactly one vertex from each edge of $M$. (The last condition means that $C \subseteq \bigcup M$ and $|C \cap e| = 1$ for each $e \in M$.)

REMARK X.3.11. Clearly if $(C, M)$ is a König covering of $G$ then $|C| = |M|$. König [148] showed that every finite bipartite graph has a König covering. From this the König duality theorem follows immediately. König coverings have also been used to generalize the König duality theorem to infinite bipartite graphs. Podewski/Steffens [202] showed that every countably infinite bipartite graph has a König covering. Aharoni [5] showed that every uncountable bipartite graph has a König covering.

Consider the following instance of the Main Question: Which set existence axioms are needed to prove the *Podewski/Steffens theorem* ("every countable bipartite graph has a König covering")? The answer is arithmetical transfinite recursion, as shown by the following theorem.

THEOREM X.3.12 (Podewski/Steffens theorem in $\mathsf{ATR}_0$). *The Podewski/Steffens theorem is equivalent over* $\mathsf{RCA}_0$ *to* $\mathsf{ATR}_0$.

PROOF. The reversal, i.e., the fact that the Podewski/Steffens theorem implies $\mathsf{ATR}_0$ over $\mathsf{RCA}_0$, is due to Aharoni/Magidor/Shore [6]. The forward direction, i.e., the fact that $\mathsf{ATR}_0$ proves the Podewski/Steffens theorem, is due to Simpson [247]. The latter proof is interesting in that it employs the method of inner models, specifically countable coded $\omega$-models of $\Sigma^1_1$-$\mathsf{AC}_0$. See also remark V.10.1. □

We now discuss perfect matchings in countable bipartite graphs.

DEFINITIONS X.3.13 (Hall condition, perfect matchings). Let $G = (X, Y, E)$ be a bipartite graph. For $A \subseteq X \cup Y$ we write $\mathrm{N}_G(A) = \{b: \{a, b\} \in E \text{ for some } a \in A\}$. $G$ is said to satisfy the *Hall condition* if $|\mathrm{N}_G(A)| \geq |A|$ for all finite $A \subseteq X \cup Y$. $G$ is said to be *locally*

*finite* if $\mathrm{N}_G(a)$ is finite for all $a \in X \cup Y$. $G$ is said to be *n-regular* if $|\mathrm{N}_G(a)| = n$ for all $a \in X \cup Y$. A matching $M$ in $G$ is said to be *perfect* if $X \cup Y = \bigcup M$, i.e., every vertex of $G$ is incident to an edge of $M$.

REMARK X.3.14. *Hall's theorem* asserts that a finite bipartite graph has a perfect matching if and only if it satisfies the Hall condition. The *marriage theorem* asserts that a finite bipartite graph which is $n$-regular for some $n \geq 1$ has a perfect matching. The marriage theorem is an easy consequence of Hall's theorem, which is an easy consequence of the König duality theorem.

THEOREM X.3.15. *The following are equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *If $G$ is a countable locally finite bipartite graph, then $G$ satisfies the Hall condition if and only if $G$ has a perfect matching.*
3. *If $G = (X, Y, E)$ is a countable bipartite graph, and if $G$ has matchings $M_1$ and $M_2$ such that $X \subseteq \bigcup M_1$ and $Y \subseteq \bigcup M_2$, then $G$ has a perfect matching.*

PROOF. This is from Hirst [117, 118]. See also McAloon [182]. □

THEOREM X.3.16. *The following are pairwise equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{WKL}_0$.
2. *If $G$ is a countable bipartite graph which is $n$-regular for some $n \geq 1$, then $G$ has a perfect matching.*
3. *If $G$ is a countable 2-regular bipartite graph, then $G$ has a perfect matching.*

PROOF. This is from Hirst [117, 118]. See also Manaster/Rosenstein [168, 169]. □

**WQO Theory.** We now consider another branch of combinatorics: well quasiordering theory.

DEFINITION X.3.17 (well quasiordering). A *quasiordering* is a set $Q$ together with a reflexive, transitive relation $\leq$ on $Q$. An *antichain* in $(Q, \leq)$ is a set of elements of $Q$ which are pairwise incomparable under $\leq$. A *well quasiordering* (abbreviated WQO) is a quasiordering which is well founded and has no infinite antichains.

REMARK X.3.18 (equivalent characterizations). For a quasiordering $(Q, \leq)$, the following conditions are pairwise equivalent.

1. $(Q, \leq)$ is well quasiordered.
2. For every sequence $\langle a_n : n \in \mathbb{N} \rangle$ of elements of $Q$, there exist $m, n \in \mathbb{N}$ such that $m < n$ and $a_m \leq a_n$.
3. For every sequence $\langle a_n : n \in \mathbb{N} \rangle$ of elements of $Q$, there exists a subsequence $\langle a_{n_k} : k \in \mathbb{N} \rangle$, $n_0 < n_1 < \cdots < n_k < \cdots$, such that $a_{n_0} \leq a_{n_1} \leq \cdots \leq a_{n_k} \leq \cdots$.
4. Every upward closed subset of $Q$ is finitely generated.

These equivalences are an easy consequence of Ramsey's theorem for exponent 2.

REMARK X.3.19 (WQO theory). There is a rich theory of well quasiorderings. For instance, the Cartesian product of two well quasiorderings is a well quasiordering, and it follows by induction that if $Q$ is a well quasiordering then so is the $m$-fold Cartesian power $Q^m$, for each $m \in \mathbb{N}$. One of the best known results in WQO theory is *Higman's theorem*: If $Q$ is a well quasiordering, then $Q^{<\mathbb{N}}$ is a well quasiordering. Here $Q^{<\mathbb{N}} = \bigcup_{m=0}^{\infty} Q^m$, the set of finite sequences of elements of $Q$, quasiordered by putting $\langle a_i : i < m\rangle \leq \langle b_j : j < n\rangle$ if and only if there exist $j_0 < \cdots < j_{m-1} < n$ such that $a_0 \leq b_{j_0}, \ldots, a_{m-1} \leq b_{j_{m-1}}$. Another well known result is *Kruskal's theorem*: If $Q$ is a well quasiordering, then the set of $Q$-labeled finite trees is well quasiordered under an appropriate quasiordering. See for example Simpson [239, 240].

THEOREM X.3.20 (Dickson's lemma and $\omega^\omega$). *The following are equivalent over* $\mathsf{RCA}_0$.

1. $\omega^\omega$ *is well ordered.*
2. *For each* $m \in \mathbb{N}$, *the* $m$*-fold Cartesian power* $\mathbb{N}^m$ *is well quasiordered.* (*This statement is sometimes known as* Dickson's lemma.)

PROOF. This follows from Simpson [245, lemma 3.6]. Note that the well orderedness of $\omega^\omega$ cannot be proved in $\mathsf{RCA}_0$, in view of theorem IX.5.4. □

REMARK X.3.21 (the Hilbert basis theorem and $\omega^\omega$). The *Hilbert basis theorem* asserts that for all countable fields $K$ and all $m \in \mathbb{N}$, any ideal in the polynomial ring $K[x_1, \ldots, x_m]$ is finitely generated. Simpson [245] has used theorem X.3.20 to show that the Hilbert basis theorem, even for $K = \mathbb{Q}$, is equivalent over $\mathsf{RCA}_0$ to well orderedness of $\omega^\omega$. See also Hatzikiriakou [110], who obtained a similar result in which the polynomial rings $K[x_1, \ldots, x_m]$ are replaced by rings of formal power series $K[[x_1, \ldots, x_m]]$. These results are of historical interest in connection with the Hilbert basis theorem's apparent lack of constructive or computational content; see Simpson [245, §1].

THEOREM X.3.22 (Higman's theorem in $\mathsf{ACA}_0$). *The following are equivalent over* $\mathsf{RCA}_0$.

1. $\mathsf{ACA}_0$.
2. *Higman's theorem.*

PROOF. This follows by combining results of Simpson [245, lemma 4.8] (see also Schütte/Simpson [215, lemma 5.2]) and Girard [90] (see remark V.6.10). □

REMARK X.3.23 (Kruskal's theorem, etc.). There are many interesting results and open problems concerning the Reverse Mathematics status of

various theorems of well quasiordering theory. Friedman (unpublished) has shown that Kruskal's theorem is not provable in $\mathsf{ATR}_0$, and that a gap embedding generalization of Kruskal's theorem is not provable in $\Pi^1_1$-$\mathsf{CA}_0$; see Simpson [239, 240, 244]. The latter result has been used in Friedman/Robertson/Seymour [77] to show that an important theorem of graph theory is not provable in $\Pi^1_1$-$\mathsf{CA}_0$. This is the Robertson/Seymour *graph minor theorem*, which asserts that the class of all finite graphs is well quasiordered under minor embeddability. See also remark IX.5.11. Some generalizations of Friedman's gap embedding theorem have been proved by Kriz [153, 154, 155]; the Reverse Mathematics status of these results is unknown.

Remark X.3.24 (minimal bad sequence lemma). An important technical lemma in WQO theory is the so-called *minimal bad sequence lemma*; see Simpson [239, 240]. Marcone and Simpson have shown that the minimal bad sequence lemma is equivalent over $\mathsf{RCA}_0$ to $\Pi^1_1$-$\mathsf{CA}_0$; see Marcone [176, theorem 6.5].

We now consider better quasiorderings, which are useful in proving that various classes of infinite structures are well quasiordered.

Definition X.3.25 (better quasiordering). A *better quasiordering* (abbreviated BQO) is a quasiordering $Q$ with the property that for any Borel mapping $f\colon [\mathbb{N}]^{\mathbb{N}} \to Q$ there exists $X \in [\mathbb{N}]^{\mathbb{N}}$ such that $f(X) \leq f(X \setminus \{\min(X)\})$. This notion is originally due to Nash-Williams [195, 196]; the formulation here is due to Simpson [237]. It can be shown that any better quasiordering is a well quasiordering, and any "natural" well quasiordering is a better quasiordering.

Definition X.3.26 (transfinite sequence theorem). If $Q$ is a quasiordering, we define $\widetilde{Q}$ to be the class of countable transfinite sequences of elements of $Q$, quasiordered by putting $\langle a_\xi\colon \xi < \alpha\rangle \leq \langle b_\eta\colon \eta < \beta\rangle$ if and only if there exist

$$\eta_0 < \cdots < \eta_\xi < \cdots < \beta \qquad (\xi < \alpha)$$

such that $a_\xi \leq b_{\eta_\xi}$ for all $\xi < \alpha$. The *transfinite sequence theorem* says that if $Q$ is better quasiordered then so is $\widetilde{Q}$. This result is due to Nash-Williams [195, 196].

Definition X.3.27 (Laver's theorem). The class of countable linear orderings may be quasiordered by putting $X \leq Y$ if and only if $X$ is order embeddable into $Y$. *Laver's theorem*, also known as *Fraïssé's conjecture*, says that the class of countable linear orderings is well quasiordered under order embeddability. This result is due to Laver [160] using BQO theory.

Remark X.3.28. A simplified exposition of the proof of the Nash-Williams transfinite sequence theorem and Laver's theorem has been given by Simpson [237]. A further simplification has been obtained by van Engelen, Miller and Steel [271].

Theorem X.3.29 (Nash-Williams theorem in $\Pi^1_1$-$\mathsf{CA}_0$). *The Nash-Williams transfinite sequence theorem is provable in* $\Pi^1_1$-$\mathsf{CA}_0$ *but is not equivalent to* $\Pi^1_1$-$\mathsf{CA}_0$.

Proof. This result is due to Marcone [176]; see also Marcone [173, 174, 175]. □

Theorem X.3.30 (reversals). *Each of Laver's theorem and the Nash-Williams transfinite sequence theorem implies* $\mathsf{ATR}_0$ *over* $\mathsf{RCA}_0$.

Proof. This is due to Shore [223], who actually showed that the following statement implies $\mathsf{ATR}_0$: For all $X \subseteq \mathbb{N}$, if $\forall n\, \mathrm{WO}((X)_n)$ then $\exists m\, \exists n\, (m \neq n \wedge (X)_m$ is order embeddable into $(X)_n)$. This is a refinement of theorem V.6.8; see also Friedman/Hirst [74, 75]. □

Remark X.3.31 (a conjecture). We conjecture that both the Nash-Williams transfinite sequence theorem and Laver's theorem are provable in $\mathsf{ATR}_0$. Clote [38, 39] has presented a proof of the transfinite sequence theorem in $\mathsf{ATR}_0$, but that proof is incorrect, as Clote has acknowledged (personal communication).

Remark X.3.32. In Downey/Lempp [48] it is shown that $\mathsf{ACA}_0$ is equivalent over $\mathsf{RCA}_0$ to a theorem of Dushnik and Miller: Every countably infinite linear ordering has a nontrivial self-embedding.

## X.4. Reverse Mathematics for $\mathsf{RCA}_0$

Throughout this book we have used $\mathsf{RCA}_0$ as our base theory for Reverse Mathematics. An important research direction for the future is to weaken the base theory. We can then hope to find mathematical theorems which are equivalent over the weaker base theory to $\mathsf{RCA}_0$, in the sense of Reverse Mathematics. There are a few results in this direction, which we now present.

Definition X.4.1 ($\mathsf{RCA}^*_0$ and $\mathsf{WKL}^*_0$). Let $\mathrm{L}_2(\exp)$ be $\mathrm{L}_2$, the language of second order arithmetic, augmented by a binary operation symbol $\exp(m, n) = m^n$ intended to denote exponentiation. We take $\exp(t_1, t_2) = t_1^{t_2}$ as a new kind of numerical term, and for each $k < \omega$ we define the $\Sigma^0_k$ and $\Sigma^1_k$ formulas of $\mathrm{L}_2(\exp)$ accordingly. We define $\mathsf{RCA}^*_0$ to be the $\mathrm{L}_2(\exp)$-theory consisting of $\mathsf{RCA}_0$ minus $\Sigma^0_1$ induction plus $\Sigma^0_0$ induction plus the exponentiation axioms: $m^0 = 1$, $m^{n+1} = m^n \cdot m$. We define $\mathsf{WKL}^*_0$ to be $\mathsf{RCA}_0$ plus weak König's lemma.

Thus we have

$$\mathsf{RCA}_0 \equiv \mathsf{RCA}_0^* + \Sigma^0_1 \text{ induction},$$

and

$$\mathsf{WKL}_0 \equiv \mathsf{WKL}_0^* + \Sigma^0_1 \text{ induction}.$$

Paralleling the results of §§IX.1–IX.3, we have:

Theorem X.4.2 (conservation theorems). *The first order part of* $\mathsf{WKL}_0^*$ *and of* $\mathsf{RCA}_0^*$ *is the* $\mathrm{L}_1(\exp)$*-theory consisting of the basic axioms* I.2.4(i) *plus the exponentiation axioms plus* $\Sigma^0_0$ *induction plus* $\Sigma^0_1$ *bounding.* $\mathsf{WKL}_0^*$ *is conservative over* $\mathsf{RCA}_0^*$ *for* $\Pi^1_1$ *sentences.* $\mathsf{WKL}_0^*$ *and* $\mathsf{RCA}_0^*$ *have the same consistency strength as* $\mathsf{EFA}$ *and are conservative over* $\mathsf{EFA}$ *for* $\Pi^0_2$ *sentences.*

Proof. See Simpson/Smith [250, §4]. □

Remark X.4.3. An interesting project would be to redo all of the known results in Reverse Mathematics using $\mathsf{RCA}_0^*$ instead of $\mathsf{RCA}_0$ as the base theory, replacing $\mathsf{WKL}_0$ by $\mathsf{WKL}_0^*$. The groundwork for this has been laid in Simpson/Smith [250], and much of it would be routine. Note however that bounded $\Sigma^0_1$ comprehension is not available in $\mathsf{RCA}_0^*$ or in $\mathsf{WKL}_0^*$ yet has played a key role in the proofs of several important results, including theorems III.7.2, III.7.6, IV.6.4, IV.7.9, IV.8.2, and V.6.8.

Theorem X.4.4 (Reverse Mathematics for $\mathsf{RCA}_0$). *The following are pairwise equivalent over* $\mathsf{RCA}_0^*$.

1. $\Sigma^0_1$ *induction*.
2. *Bounded* $\Sigma^0_1$ *comprehension*.
3. *For every countable field* $K$, *every polynomial* $f(x) \in K[x]$ *has only finitely many roots in* $K$.
4. *For every countable field* $K$, *every polynomial* $f(x) \in K[x]$ *has an irreducible factor.*
5. *For every countable field* $K$, *every polynomial* $f(x) \in K[x]$ *can be factored into finitely many irreducible polynomials.*
6. *Every finitely generated vector space over* $\mathbb{Q}$ (*or over any countable field*) *has a basis.*
7. *Every finitely generated, torsion-free Abelian group is of the form* $\mathbb{Z}^m$, $m \in \mathbb{N}$.
8. *The structure theorem for finitely generated Abelian groups.*

Proof. The proof of $1 \leftrightarrow 2$ has been sketched in remark II.3.11. The equivalences $1 \leftrightarrow 2$, $1 \leftrightarrow 3$, $1 \leftrightarrow 4$ and $1 \leftrightarrow 5$ are from Simpson/Smith [250]. The equivalence $1 \leftrightarrow 6$ is due to Friedman (unpublished). Compare theorem III.4.3. The equivalences $1 \leftrightarrow 6$, $1 \leftrightarrow 7$ and $1 \leftrightarrow 8$ are proved in Hatzikiriakou [107, 108]. □

## X.5. Conclusions

In this appendix we have mentioned a number of additional results and problems in Reverse Mathematics for $\mathsf{RCA}_0$, $\mathsf{WWKL}_0$, $\mathsf{WKL}_0$, $\mathsf{ACA}_0$, $\mathsf{ATR}_0$, and $\Pi^1_1$-$\mathsf{CA}_0$. The mathematical statements were drawn from several branches of mathematics: measure theory, separable Banach space theory, Ramsey theory, matching theory, well quasiordering theory, and countable algebra. We have also made a start on the project of weakening the base theory in Reverse Mathematics.
